Abstract

AutoCorres2 is a tool to facilitate the verification of C programs within Isabelle [5]. It is a fork of [AutoCorres](#).

Contents

1	Introduction	11
I	Library	12
2	Misc. Definitions and Lemmas	13
2.1	Take, drop, zip, <i>list-all</i> etc rules	58
3	ML Antiquotations	68
3.1	Building terms: <i>mk-term</i>	68
3.2	Term pattern: <i>term-pat</i>	69
3.2.1	Example	79
3.3	ML Antiquotation to Match and Instantiate (recombine) cterms and terms	81
3.4	Record Antiquotation	90
3.4.1	Motivation	90
3.4.2	Example	91
3.4.3	Implementation	91
3.4.4	Examples	94
3.5	Various Antiquotations	96
3.5.1	Antiquotations for terms with schematic variables	96
3.5.2	Antiquotation for types with schematic variables	96
4	Proof Tools	98
4.1	Tools for handling Tuples	98
4.1.1	Antiquotations for terms with schematic variables	98
4.2	Tools for intro-rule based term synthesis <i>synthesize-rules</i>	129
4.2.1	Commands	129
4.2.2	ML Antiquotations	130
4.2.3	Attributes	130
5	Rule by Method	132
5.1	Tagging	145
5.1.1	Basic Definitions and Theorems	145
5.1.2	Conversions	147

5.1.3	Globbering	151
5.1.4	Reordering Subgoals	152
5.1.5	<i>subgoalT</i> and <i>subgoalsT</i> , and <i>prefersT</i>	153
6	Verification Condition Generator <i>runs-to-vcg</i>	159
6.1	Marked Assumptions	159
6.2	<i>THEN-ALL-NEW-FORWARD</i>	160
6.3	Basic VCG	161
6.4	Setup for Tagging	165
6.5	<i>runs-to-vcg</i>	166
6.6	Check	166
7	Proof Methods	167
7.1	Debugging methods	167
7.2	Simple Combinators	167
7.3	Advanced combinators	172
7.3.1	Protecting goal elements (assumptions or conclusion) from methods	172
7.3.2	Safe subgoal folding (avoids expanding meta-conjuncts)	172
7.4	Utility methods	174
7.4.1	Finding a goal based on successful application of a method	174
7.4.2	Remove redundant subgoals	175
7.5	Attribute methods (for use with <i>rule-by-method</i> attributes)	177
7.6	Shortcuts for <i>prove-prop.</i>	177
8	Option Monad (State Reader)	179
8.1	"While" loops over option monad.	185
8.2	Lift <i>option-while</i> to the (<i>'a, 's</i>) <i>lookup</i> monad	187
9	Mutual CCPO Recursion <i>fixed-point</i>	197
9.1	Relate orders between locale and type classes	197
9.2	Prove admissibility of <i>corresXF</i>	199
II	C-Parser	202
10	Theory Variants for Target Architectures via <i>L4V-ARCH</i>	203
11	Unified Memory Model (UMM)	206
11.1	More Word Lemmas	206
11.2	Distinct Proposition	224
11.3	Type setup	234
11.3.1	Pointers	234
11.3.2	Raw heap	236

11.4	Intervals	236
11.5	<i>dt-tuple</i> : a reimplementa- tion of 3 item tuples	236
11.6	Properties of pointers	237
11.7	Properties of the raw heap	238
11.8	Properties of intervals	238
11.9	C types setup	242
11.10	<i>super-update-bs</i>	277
11.11	Rest	278
11.12	Words and Pointers	346
11.13	Finite Cartesian Products	362
11.14	Auxiliary Theorems	369
11.15	Legacy definition <i>fg-cons</i>	371
11.16	Lense definition using an update function <i>lense</i>	371
11.17	Update for functions	373
11.18	Scenes	373
11.19	More properties of maps plus map disjunction.	509
11.19.1	Properties of maps not related to restriction	510
11.19.2	Properties of map restriction	511
11.20	Definitions	514
11.21	Properties of ($'-$)	514
11.22	Properties of map disjunction	514
11.22.1	Map associativity-commutativity based on map disjunction	515
11.22.2	Basic properties	516
11.22.3	Map disjunction and addition	516
11.22.4	Map disjunction and updates	518
11.22.5	Map disjunction and (\subseteq_m)	519
11.22.6	Map disjunction and restriction	520
11.23	<i>sep-point-tac</i>	642
11.24	<i>sep-exists-tac</i>	643
11.25	<i>sep-select-tac</i>	644
11.26	Instantiation, inferring type instantiation from term instantiation.	687
11.27	(Partial) Pointer Lenses	716
11.27.1	<i>pointer-lense</i>	716
11.27.2	<i>partial-pointer-lense</i>	716
11.28	<i>heap-upd</i> and <i>heap-upd-list</i>	890
11.29	<i>heap-upd</i>	890
11.30	<i>merge-ti</i>	893
11.30.1	<i>merge-ti-list</i>	898
12	More Building Blocks for our C- Language Model	902
12.1	addr bounds	902
12.2	More Heap Typing	903

12.2.1	Heap type tag and valid simple footprint	905
12.3	Pointers to local (stack) variables	910
12.4	Misc derived language elements	974
13	Packed Types (no implicit padding)	993
13.1	Underlying definitions for the class axioms	993
13.2	Lemmas about <i>td-fafu-idem</i>	994
13.2.1	<i>td-fa-hi</i>	998
13.3	Simp rules for deriving packed props from the type combinators	1000
13.3.1	<i>td-fafu-idem</i>	1000
13.3.2	<i>td-fa-hi</i>	1003
13.4	The type class and simp sets	1005
13.5	Instances	1006
13.6	Theorems about packed types	1007
13.6.1	<i>td-fa-hi</i>	1007
13.6.2	<i>td-fafu-idem</i>	1007
13.6.3	Proof automation for packed types	1014
13.7	Prettier Printing for Programs	1016
13.8	Modelling Local Variables	1028
14	Setup Lex / Yacc and Translation from C to Simpl	1045
15	Misc. Lemmas	1064
15.1	Abbreviations and helpers	1064
15.2	Basic operations	1064
15.2.1	<i>clift</i>	1064
15.2.2	<i>h-val</i>	1065
15.2.3	<i>h-t-valid</i>	1065
15.3	<i>field-lvalue</i>	1066
15.3.1	<i>heap-update</i>	1066
15.3.2	<i>c-guard</i>	1067
15.3.3	<i>clift</i>	1067
15.3.4	<i>cparent</i>	1068
15.3.5	<i>h-val</i>	1070
15.3.6	<i>h-t-valid</i>	1071
15.3.7	Type Combinators and Padding	1074
15.3.8	The orphanage: miscellaneous lemmas pulled up to (roughly) where they belong.	1075
III	AutoCorres	1100
16	Spec-Monad	1101
16.1	<i>rel-map</i> and <i>rel-project</i>	1101

Chapter 1

Introduction

AutoCorres2 is a tool to facilitate the verification of C programs within Isabelle [5]. It is a fork of AutoCorres: <https://trustworthy.systems/projects/OLD/autocorres/>. Here some quick links into the document:

- Quickstart guide for users ([chapter 25](#)): `doc/quickstart/Chapter1_MinMax.thy`
- Background information, internals and some history of AutoCorres ([chapter 26](#)): `doc/AutoCorresInfrastructure.thy`
- C-Parser
 - Some internals ([chapter 27](#)): `c-parser/CTranslationInfrastructure.thy`
 - Original documentation (outdated) ([chapter 28](#)): The supported subset of C is extended. Moreover, the C-parser is integrated into Isabelle/ML and no standalone C-parser is supplied. The description of the design principles is still valid: `c-parser/doc/ctranslation_body.tex`

ML Antiquotations

3.1 Building terms: *mk-term*

```
theory MkTermAntiquote  
imports  
  Pure  
begin
```

mk-term: ML antiquotation for building and splicing terms.
See `MkTermAntiquote_Tests.thy` for examples and tests.

ML-file *mkterm-antiquote.ML*

```
end
```

mk-term: ML antiquotation for building and splicing terms.

```
theory MkTermAntiquote-Tests  
imports  
  MkTermAntiquote  
  Main  
begin
```

Basic usage: `@{mk-term pattern... (vars, ...)} (args, ...)`

The vars should match schematic vars in the pattern, and they are substituted with the given arguments.

Template vars can include type vars, and they should be applied to type arguments.

```
ML-val ‹  
@{assert} (@{mk-term ?x (x)} @term x::'a)  
  = @term x::'a);  
  
@{assert} (@{mk-term 0::'a::zero ('a)} @typ nat)  
  = @term 0::nat);
```

(* Tuples are used to pass multiple arguments *)

```
@{assert} (@{mk-term ?xs @ ?ys (ys, xs)} (@term [True]}, @term [False]))
```

```

    = @term [False] @ [True]);
  >

```

Note that *mk-term* does not perform full type inference automatically. If some argument types are mismatched or too general, the output may be inconsistent. This may change in future versions.

```

ML-val <
@assert (@mk-term ?x = ?y (x, y)) (@term 0::'a::zero, @term Suc 0)
    = (Const (@const-name HOL.eq), @typ 'a::zero => 'a => bool) $
      @term 0::'a::zero $ @term Suc 0))
  >

```

Besides static checking, using *mk-term* also gives a reusable template:

```

ML-val <
let
  val mk-pair: term*term -> term = @mk-term (?a, ?b) (a, b);
in
  @assert (mk-pair (@term ()), @term True) = @term ((), True));
  @assert (mk-pair (@term int 1), @term int 2)
    = @term (int 1, int 2))
end;
  >

```

end

3.2 Term pattern: *term-pat*

theory *TermPatternAntiquote* **imports**

  ((Args.context -- Scan.lift Parse.embedded-inner-syntax)
   >> uncurry Term-Pattern-Antiquote.term-pattern-antiquote)))
>

end

theory TermPatternAntiquote-Tests
imports
  TermPatternAntiquote
  Main
begin
  Term pattern matching utility.
  Instead of writing monstrosities such as

```

```

case t of
  Const ("Pure.imp", _) $
    P $
    Const (@{const_name Trueprop}, _) $
      (Const ("HOL.eq", _) $
        (Const (@{const_name "my_func"}, _) $ x) $ y)
=> (P, x, y)

```

simply use a term pattern with variables:

```

case t of
  @{term_pat "PROP ?P \<Longrightarrow> my_func ?x = ?y"}
=> (P, x, y)

```

Each *term-pat* generates an ML pattern that can be used in any case-expression or name binding. The ML pattern matches directly on the term datatype; it does not perform matching in the Isabelle logic.

Schematic variables in the pattern generate ML variables. The variables must obey ML's pattern matching rules, i.e. each can appear only once.

Due to the difficulty of enforcing this rule for type variables, schematic type variables are ignored and not checked.

Example: evaluate arithmetic expressions in ML.

```

ML-val <
fun eval-num @{term_pat numeral ?n} = HOLogic.dest-numeral n
| eval-num @{term_pat Suc ?n} = eval-num n + 1
| eval-num @{term_pat 0} = 0
| eval-num @{term_pat 1} = 1
| eval-num @{term_pat ?x + ?y} = eval-num x + eval-num y
| eval-num @{term_pat ?x - ?y} = eval-num x - eval-num y
| eval-num @{term_pat ?x * ?y} = eval-num x * eval-num y
| eval-num @{term_pat ?x div ?y} = eval-num x div eval-num y
| eval-num t = raise TERM (eval-num, [t]);

```

```

eval-num @{term (1 + 2) * 3 - 4 div 5}
>

```

Regression test: backslash handling

```

ML-val <
val @{term_pat  $\alpha$ } = @{term  $\alpha$ }
>

```

Regression test: special-casing for dummy vars

```

ML-val <
val @{term_pat  $\lambda x y. \_$ } = @{term  $\lambda x y. z$ }
>

```

end

  )

```

The antiquotation yields a function that matches the schematic variables of a pattern with a `cterm`. The matched parts are returned as `cterm` in a record, where the field name is derived from the original schematic variable name. Moreover a function `instantiate` is returned that can be used to instantiate the matched pattern with other `cterms`.

The antiquotation makes use of the kernel operations `Thm.match / Thm.first_order_match`. These operations are efficient in the sense that no costly re-certification of subterms has to be performed.

```

ML-val <
val {f, g, instantiate, ct-} = @{cterm-match λx. ?f x + ?g x} @{cterm λx. p x +
q x}
val twisted = instantiate {f = g, g = f}
  >

```

Dummy pattern can also be supplied. The matched values for the dummy patterns are not part of the matching result but still considered in *instantiate*.

```

ML-val <
val {f, g, instantiate, ...} = @{\cterm-match \lambda x. ?f x + ?g x + -} @{\cterm \lambda x. p
x + q + r x}
val twisted = instantiate {f = g, g = f}
>

```

```

ML-val <
val {f, g, ...} = @{\cterm-match \lambda x. ?f x + ?g x} @{\cterm \lambda x. p x + q}
>

```

```

ML-val <
val {f1, f2, ...} = @{\cterm-match \lambda x. ?f1.0 x + ?f2.0 x} @{\cterm \lambda x. p x + q}
>

```

```

ML-val <
val {f, ...} = @{\cterm-match \lambda x. ?f x} @{\cterm <\lambda x. f>}
>

```

There is also a variant for first-order-matching.

```

ML-val <
let
  val - = @{\cterm-match (fo) \lambda x. ?f x} @{\cterm <\lambda x. f>}
in
  ()
end
handle Pattern.MATCH => tracing (this is not first order)
>

```

There is also the corresponding antiquotations for plain terms.

```

ML-val <
val {f, g, instantiate, ...} = @{\match \lambda x. ?f x + ?g x} @{\theory} @{\term \lambda x. p x
+ q x}
val twisted = instantiate {f = g, g = f}
>

```

There you can also see the different workings of first-order-matching. Note the eta expanded match result in the higher-order variant before.

```

ML-val <
val {f, g, instantiate, ...} = @{\match (fo) \lambda x. ?f x + ?g x} @{\theory} @{\term \lambda x.
p x + q x}
val twisted = instantiate {f = g, g = f}
>

```

There is a variant for ML-pattern-matching. This means, that before using first-order-matching it is tested whether the term actually matches the underlying ML-pattern with ML-pattern matching.

```

ML-val <
val {f, g, instantiate, ...} = @{cterm-match (ml) λx. ?f x + ?g x} @{cterm λx. p
x + q x}
val twisted = instantiate {f = g, g = f}
>

```

Note that as with all ML-Patterns a variable might only appear once. So the following example is a valid first-order or higher-order pattern but not a valid ML-pattern

```

ML-val <
val {f, ...} = @{cterm-match ?f + ?f} @{cterm a + a}
>

```

This is what happens conceptually in the expanded antiquotation.

```

ML-val <
val ctxt = @{context}
val pat = Proof-Context.read-term-pattern ctxt λx. ?f x + ?g x |> Thm.cterm-of
ctxt
val [g-var, f-var] = Term.add-vars (Thm.term-of pat) [] |> map (Thm.cterm-of
ctxt o Var)
val env = Thm.match (pat, @{cterm λx. a x + b})
val [f, g] = map (Thm.instantiate-cterm env) [f-var, g-var]
val tenv = fst env
val [f-var, g-var] = map (Thm.instantiate-cterm (tenv, Vars.empty)) [f-var, g-var]
fun instantiate {f, g} =
  Match-Cterm.cterm-instantiate Position.none env [f-var, g-var] [f, g]
val res = {f = f, g = g, instantiate = instantiate}
val x = instantiate {f=g, g=f}
>

```

With the verbose flag you can see the generated function.

```

declare [[verbose=5]]

```

```

ML-val <
val X = @{cterm-match ?X + -} @{cterm <a + a>}
>

```

```

ML-val <
val X = @{cterm-morph-match ?X + -} Morphism.identity @{cterm <a + a>}
>

```

```

ML-val <
val X = @{morph-match ?X + -} Morphism.identity @{theory} @{term <a + a>}
>

```

```
ML-val <
val X = @{cterm-match <?X + ->} @{cterm <a + a>}
>
```

```
declare [[verbose=0]]
```

```
end
```

3.4 Record Antiquotation

```
theory ML-Record-Antiquotation
```

```
  imports Main
```

```
begin
```

3.4.1 Motivation

A shortcoming of ML records is the lack of proper update / map functions for the record fields. Manually defining those update functions is considered as painful, as it requires 'quadratic' editing when adding a new field: - add the new field to every record pattern (in every already defined update / map function) - add a new update / map function for the field.

Various workarounds have been proposed. E.g. - Using mutable references as fields to allow for destructive updates - Fancy higher order function-combinators (Fold): <http://mlton.org/FunctionalRecordUpdate>

Here we develop yet another solution. We provide a ML-Antiquotation that generates the definitions.

For a record specification as datatype `datatype 'a foo = Foo {f1:'a, f2:bool}` it generates the datatype as specified with one constructor `Foo` wrapping the record and additionally all the 'canonical' functions:

- `make_foo`
- `dest_foo`
- `get_f1`
- `get_f2`
- `map_f1`
- `map_f2`

3.4.2 Example

```
ML-val <
datatype 'a foo = Foo of {f1:'a, f2:bool};

val make-foo = Foo;
fun dest-foo (Foo r) = r;

fun get-f1 (Foo r) = #f1 r;
fun get-f2 (Foo r) = #f2 r;

fun map-f1 f (Foo {f1, f2}) =
  Foo {f1 = f f1, f2 = f2};
fun map-f2 f (Foo {f1, f2}) =
  Foo {f1 = f1, f2 = f f2};
>
```

3.4.3 Implementation

```
ML <

structure ML-Record-Antiquotation =
struct

fun remove-comments s =
  let
    val unbalanced-comments-msg = unbalanced ML comments (* ... *)
    fun err-unbalanced () = error unbalanced-comments-msg

    fun rem n [] = if n = 0 then [] else err-unbalanced ()
      | rem n (::*::xs) = rem (n + 1) xs
      | rem n (*::)xs = if n > 0 then rem (n - 1) xs else err-unbalanced ()
      | rem n (x::xs) = if n = 0 then x::rem n xs else rem n xs
  in
    s |> Symbol.explode |> rem 0 |> implode
  end

fun to-upper-first s =

  fun ^ get-name field-name ^ ( ^ constr ^ r) = # ^ field-name ^ r;;

fun mk-gets constr fields =
  fields |> map fst |> map (mk-get constr) |> cat-lines

fun mk-record-datatype-declaration add-decl s =

```

```

let
  val ((lhs, rhs), record as (params, rec-name), constr, fields) = parse-record-declaration
s;
  val decl = lhs ^ = ^ rhs ^ ;;
  val make = val ^ make-name rec-name ^ = ^ constr ^ ;;
  val dest = fun ^ dest-name rec-name ^ ( ^ constr ^ r) = r;;
  val gets = mk-gets constr fields;
  val maps = mk-maps constr fields;
  fun cond-cons P a xs = if P then a::xs else xs
in
  cat-lines (cond-cons add-decl decl [make, dest, gets, maps])
end

end
>

```

Test the parser and its output.

```

ML-val <
let
  val test = datatype 'a foo = Foo of {fld1:int, fld2:'a}
in writeln (ML-Record-Antiquotation.mk-record-datatype-declaration true test) end
>

```

```

setup <
ML-Antiquotation.inline-embedded (Binding.make (record,here))
(Scan.lift Parse.embedded-input >> (fn source =>
  let
    val - = ML-Lex.read-source source; — provide some markup as side effect
    val sanitized-str = fst (Input.source-content source) |> ML-Lex.tokenize |>
ML-Lex.flatten
  in ML-Record-Antiquotation.mk-record-datatype-declaration true sanitized-str
end))
>

```

3.4.4 Examples

```

ML-val <

structure JustAStruct = struct
datatype bar = Bar of int;

@{record <datatype 'a foo =
  Foo of {f1:'a (* comments are removed *),
    f2:bar }
}>}

val my-foo = Foo {f1 = 1, f2 = Bar 42};
val my-foo1 = map-f1 (K (Bar 44)) my-foo;
val t = get-f1 my-foo1

```

```

val t1 = make-foo {f1=3, f2=Bar 4}
val t2 = dest-foo t1

@{record <datatype foo2 = Foo2 of {f3:int foo}>}

end
>

```

Note that the markup of the datatype declaration is limited to basic Lex-markup. Experiments with explicitly evaluating the datatype with e.g. the `ML` function failed. The issue there is that the `ML` function is not evaluated at the point (aka context) exactly in the text position, but with the context of the surrounding `ML` command.

The following examples try to illustrate the issues.

Works as expected, as every type referred to in the datatype spec is already known at the beginning of the **ML-val** command.

```

ML-val <
val - = ML <datatype foo = Foo of int>;
>

```

The following fails as 'bar' is not known at the beginning of the context.

```

ML-val <
datatype bar = Bar of int
val - = ML <datatype foo = Foo of bar>
handle ERROR x => warning x
>

```

Adding a semicolon after the definition of bar helps. There the semicolon marks the end of an "evaluation / compilation chunk". So `ML` is evaluated within an already augmented `ML`-context that knows about `bar`.

```

ML-val <
datatype bar = Bar of int;
val - = ML <datatype foo = Foo of bar>
>

```

In the context of a structure the semicolon is not enough.

```

ML-val <

structure InAStruct =
struct
datatype bar = Bar of int;

val - = ML <datatype foo = Foo of bar>
handle ERROR x => warning x
end

>

```

end

```

Chapter 4

Proof Tools

```
theory Tuple-Tools
```

```
imports Main
  Misc-Antiquotation
  TermPatternAntiquote
  ML-Fun-Cache
```

```
begin
```

4.1 Tools for handling Tuples

The tools are supposed to help simplifying expressions containing *case-prod* constructions, like $\lambda(w, x, y, z). f w x y z$.

- Simprocs for single step splitting and simplification of tuples / *case-prods* instead of repeated application of the built-in variants for pairs
- Looper for the simplifier to instantiate f in $f (a, b, c)$ with $\lambda(a, b, c). g a b c$

4.1.1 Antiquotations for terms with schematic variables

```
setup <
let
  val parser = Args.context -- Scan.lift Parse.embedded-inner-syntax
  fun pattern (ctxt, str) =
    str |> Proof-Context.read-term-pattern ctxt
        |> ML-Syntax.print-term
        |> ML-Syntax.atomic
in
  ML-Antiquotation.inline @{binding pattern} (parser >> pattern)
end
```

```

>
ML <@{pattern  $\lambda(a,b,c). ?g a b c$ }>

setup <
  let
  type style = term -> term;

  fun pretty-term-style ctxt (style: style, t) =
    Document-Output.pretty-term ctxt (style t);

  val basic-entity = Document-Output.antiquotation-pretty-source;

  in
  (* Document antiquotation that allows schematic variables *)
  (basic-entity binding <pattern> (Term-Style.parse -- Args.term-pattern) pretty-term-style)
  end
>

```

Unification only works modulo ordinary beta reduction but does not succeed on tupled-beta reduction. For example the simplifier will not find an instantiation for the variable $?c$

```

schematic-goal  $\bigwedge a b. (\text{case } (a, b) \text{ of } (x, y) \Rightarrow f x y) \equiv ?c (a, b)$ 
  apply simp
  oops

```

Such equations can typically occur in congruence rules when a pair is splitted by $(\bigwedge x. PROP ?P x) \equiv (\bigwedge a b. PROP ?P (a, b))$.

```

lemma tuple-up-eq-trivial:  $f r \equiv (\lambda x. f x) r$ 
  by simp

```

```

thm tuple-up-eq-trivial

```

```

lemma tuple-up-eq2:  $f (\text{fst } r) (\text{snd } r) \equiv (\text{case } r \text{ of } (x1, x2) \Rightarrow f x1 x2)$ 
  by (simp add: split-def)

```

Constant to explicitly trigger splitting by `simproc SPLIT_simproc` below

```

definition SPLIT :: 'a::{}  $\Rightarrow$  'a
  where SPLIT P  $\equiv$  P

```

```

lemma SPLIT-cong:  $PROP \text{SPLIT } P \equiv PROP \text{SPLIT } P$ 
  by simp

```

```

lemma case-prod-out:  $(\lambda r. f ((\lambda(a,b). (g a b)) r)) = (\lambda(a, b). f (g a b))$ 
  apply (rule ext)
  apply (simp add: split-paired-all)
  done

```

```

lemma case-prod-eta-contract:  $(\lambda x. (\text{case-prod } s) x) \equiv (\text{case-prod } s)$ 
  by simp

```

definition *ETA-TUPLED* :: ('a ⇒ 'b) ⇒ ('a ⇒ 'b)
where *ETA-TUPLED* f ≡ f

lemma *ETA-TUPLED-trans*: f ≡ g ⇒ *ETA-TUPLED* f ≡ g
by (*simp add: ETA-TUPLED-def*)

Add the congruence rule *SPLIT PROP ?P ≡ SPLIT PROP ?P* to the simpset together with the simproc to avoid descending into *P* before the split.

(* For a goal with a schematic variable of the form

$?f(x_1, x_2, \dots, x_n)$

as it might occur in an congruence rule

$\bigwedge \dots x_1 \dots x_n \dots . ?X \equiv ?f(x_1, x_2, \dots, x_n) \dots$

instantiate $?f$ to $\lambda(x_1, x_2, \dots, x_n). ?f' x_1 x_2 \dots x_n \dots$

Currently only instantiates the first such $?f$ it finds by a canonical traversal of the term.

The tupled argument does not have to be the first argument, also works for the more general case

like $?f\ t1\ t2\ (x1,x2,\dots,xn)\ t3\ t4$

`tuple-inst-tac` can be used as a looper.

(*
 * Generates a custom rule with the tuple arity of an abstracted variable. The
 * position of the
 * abstraction is specified in the pattern (which is also used as simproc pattern).
 * Every real variable
 * in that pattern (besides the dummy pattern -) will be considered as an abstraction
 * to split. E.g.
 * thm:  $\bigwedge v. P (?y v) \implies \text{seq } ?x (\lambda x. ?y x)$  with pattern  $\text{seq } - ?Y$ 
 * When this is applied to a term  $\text{seq } x (\lambda(a,b,c). ?y a b c)$  a rule of arity 3 will be
 * generated:
 *  $\bigwedge a b c. P (?y a b c) \implies \text{seq } ?x (\lambda(a, b, c). ?y a b c)$  which can be matched with
 * the term.

  The purpose of the option scanner is to provide an interface to scan lists
  of options (key / value) for toplevel commands. As values may have different
  types the idea is that the collection of options is represented by an record of
  optional values. This record can be provided individually for each command.
  The initial option-record "empty" has every component assigned to NONE. To
  be able to specify all options in a single list, we represent a single parser
  / scanner for a field as an update function for the option-record, which is
  composed by the map-functions for the record fields. So we can preserve
  different types for parsing individual fields (and do not need an universal
  value type), while the specification list is a monotype.

      timed-tac st' (method-evaluate m ctxt facts st');

in SIMPLE-METHOD tac [] end)
>

```

```

method repeat-new methods m = (m ; (repeat-new <m>)?)

```

The following *fails* and *succeeds* methods protect the goal from the effect of a method, instead simply determining whether or not it can be applied to the current goal. The *fails* method inverts success, only succeeding if the given method would fail.

```

method-setup fails =
  <Method.text-closure >> (fn m => fn ctxt => fn facts =>
  let
    fun fail-tac st' =
      (case Seq.pull (method-evaluate m ctxt facts st') of
        SOME - => Seq.empty
        | NONE => Seq.single st')

in SIMPLE-METHOD fail-tac facts end)
>

```

```

method-setup succeeds =

```

```

<Method.text-closure >> (fn m => fn ctxt => fn facts =>
  let
    fun can-tac st' =
      (case Seq.pull (method-evaluate m ctxt facts st') of
        SOME (st'',-) => Seq.single st'
        | NONE => Seq.empty)

    in SIMPLE-METHOD can-tac facts end)
>

```

This method wraps up the "focus" mechanic of match without actually doing any matching. We need to consider whether or not there are any assumptions in the goal, as premise matching fails if there are none.

If the *fails* method is removed here, then backtracking will produce a set of invalid results, where only the conclusion is focused despite the presence of subgoal premises.

```

method focus-concl methods m =
  ((fails <erule thin-rl>, match conclusion in - => <m>)
  | match premises (local) in H:- (multi) => <m>)

```

repeat applies a method a specific number of times, like a bounded version of the '+' combinator.

usage: apply (repeat n *text*)

- Applies the method *text* to the current proof state n times. - Fails if *text* can't be applied n times.

```

ML <
  fun repeat-tac count tactic =
    if count = 0
    then all-tac
    else tactic THEN (repeat-tac (count - 1) tactic)
>

```

```

method-setup repeat = <
  Scan.lift Parse.nat -- Method.text-closure >> (fn (count, text) => fn ctxt =>
  fn facts =>
    let val tactic = method-evaluate text ctxt facts
        in SIMPLE-METHOD (repeat-tac count tactic) facts end)
>

```

notepad begin

fix A B C

assume *assms*: A B C

repeat: simple repeated application.

have A ∧ B ∧ C ∧ True

repeat: fails if method can't be applied the specified number of times.

apply (fails <repeat 4 <rule conjI, rule assms>>)

```
apply (repeat 3 ⟨rule conjI, rule assms⟩)
by (rule TrueI)
```

repeat: application with subgoals.

```
have A ∧ A B ∧ B C ∧ C
apply –
```

We have three subgoals. This *repeat* call consumes two of them.

```
apply (repeat 2 ⟨rule conjI, (rule assms)+⟩)
```

One subgoal remaining...

```
apply (rule conjI, (rule assms)+)
done
```

end

Literally a copy of the parser for *subgoal-tac* composed with an analogue of **prefer**.

Useful if you find yourself introducing many new facts via *subgoal-tac*, but prefer to prove them immediately rather than after they're used.

```
setup ⟨
  Method.setup binding ⟨prop-tac⟩
  (Args.goal-spec -- Scan.lift (Scan.repeat1 Parse.embedded-inner-syntax --
Parse.for-fixes) >>
  (fn (quant, (props, fixes)) => fn ctxt =>
    (SIMPLE-METHOD'' quant
      (EVERY' (map (fn prop => Rule-Insts.subgoal-tac ctxt prop fixes) props)
        THEN'
          (K (prefer-tac 2))))))
  insert prop (dynamic instantiation), introducing prop subgoal first
  ⟩
```

```
notepad begin {
  fix xs
  assume assms: list-all even (xs :: nat list)
```

```
  from assms have even (sum-list xs)
  apply (induct xs)
  apply simp
```

Inserts the desired proposition as the current subgoal.

```
apply (prop-tac list-all even xs)
subgoal by simp
```

The prop *list-all even xs* is now available as an assumption. Let's add another one.

```
apply (prop-tac even (sum-list xs))
subgoal by simp
```

Now that we've proven our introduced props, use them!

```

apply clarsimp
done
}
end

```

7.3 Advanced combinators

7.3.1 Protecting goal elements (assumptions or conclusion) from methods

```

context

```

```

end

```

```

notepad begin

```

```

fix  $D C$ 
assume  $DC:D \implies C$ 
have  $D \wedge D \implies C \wedge C$ 
apply (only-asm  $\langle \textit{simp} \rangle$ ) — stash conclusion before applying method
apply (only-concl  $\langle \textit{simp add: DC} \rangle$ ) — hide premises from method
by (rule DC)

```

```

end

```

7.3.2 Safe subgoal folding (avoids expanding meta-conjuncts)

Isabelle's goal mechanism wants to aggressively expand meta-conjunctions if they are the top-level connective. This means that *fold-subgoals* will immediately be unfolded if there are no common assumptions to lift over.

To avoid this we simply wrap conjunction inside of conjunction' to hide it from the usual facilities.

context begin

definition

conjunction' :: *prop* ⇒ *prop* ⇒ *prop* (**infixr** &~& 2) **where**
conjunction' *A B* ≡ (*PROP A* &&& *PROP B*)

In general the context antiquotation does not work in method definitions. Here it is fine because `Conv.top_sweep_conv` is just over-specified to need a `Proof.context` when anything would do.

method *safe-meta-conjuncts* =

raw-tactic
 ⟨*REPEAT-DETERM*
 (*CHANGED-PROP*
 (*PRIMITIVE*
 (*Conv.gconv-rule* ((*Conv.top-sweep-conv* (*K* (*Conv.rewr-conv* @{*thm conjunction'-def*[*symmetric*]})) @{*context*})) 1)))⟩

method *safe-fold-subgoals* = (*fold-subgoals* (*prefix*), *safe-meta-conjuncts*)

lemma *atomize-conj'* [*atomize*]: (*A* &~& *B*) == *Trueprop* (*A* & *B*)
 by (*simp add: conjunction'-def*, *rule atomize-conj*)

lemma *context-conjunction'I*:

PROP P ⇒ (*PROP P* ⇒ *PROP Q*) ⇒ *PROP P* &~& *PROP Q*

apply (*simp add: conjunction'-def*)

apply (*rule conjunctionI*)

apply *assumption*

apply (*erule meta-mp*)

apply *assumption*

done

lemma *conjunction'I*:

PROP P ⇒ *PROP Q* ⇒ *PROP P* &~& *PROP Q*

by (*rule context-conjunction'I*; *simp*)

lemma *conjunction'E*:

assumes *PQ*: *PROP P* &~& *PROP Q*

assumes *PQR*: *PROP P* ⇒ *PROP Q* ⇒ *PROP R*

shows

PROP R

apply (*rule PQR*)

apply (*rule PQ*[*simplified conjunction'-def*, *THEN conjunctionD1*])

by (*rule PQ*[*simplified conjunction'-def*, *THEN conjunctionD2*])

end

notepad begin

```

fix  $D C E$ 

assume  $DC: D \wedge C$ 
have  $D C \wedge C$ 
apply –
apply (safe-fold-subgoals, simp, atomize (full))
apply (rule DC)
done

end

```

7.4 Utility methods

7.4.1 Finding a goal based on successful application of a method

```

method-setup find-goal =
  <Method.text-closure >> (fn m => fn ctxt => fn facts =>
    let
      fun prefer-first i = SELECT-GOAL
        (fn st' =>
          (case Seq.pull (method-evaluate m ctxt facts st') of
            SOME (st'',-) => Seq.single st''
          | NONE => Seq.empty)) i THEN prefer-tac i

    in SIMPLE-METHOD (FIRSTGOAL prefer-first) facts end)

```

Ensure that the proof state is in a certain case of a case distinction:

```

method in-case for  $x = \text{match premises in } t = x \text{ for } t \Rightarrow \text{succeed}$ 

```

Focus on a case in a case distinction:

```

method find-case for  $x = \text{find-goal } \langle \text{in-case } x \rangle$ 

```

notepad begin

```

fix  $A B$ 
assume  $A: A$  and  $B: B$ 

have  $A A B$ 
  apply (find-goal <match conclusion in  $B \Rightarrow \langle - \rangle$ >)
  apply (rule B)
  by (rule A)+

have  $A \wedge A A \wedge A B$ 
  apply (find-goal <fails <simp>>) — find the first goal which cannot be simplified
  apply (rule B)
  by (simp add: A)+

have  $B A A \wedge A$ 

```

apply (*find-goal* \langle succeeds \langle simp $\rangle\rangle$) — find the first goal which can be simplified (without doing so)

apply (*rule conjI*)
by (*rule A B*) $+$

fix $x::'a$ **and** $S :: nat \Rightarrow 'a$ **and** $T R$

have

$x = T \Longrightarrow A$
 $x = S 10 \Longrightarrow B$
 $x = R \Longrightarrow B$

apply –

apply (*find-case S ?n*)
apply (*fails* \langle in-case $R\rangle$)
apply (*in-case S ?n*)
by (*rule A B*) $+$

end

7.4.2 Remove redundant subgoals

Tries to solve subgoals by assuming the others and then using the given method. Backtracks over all possible re-orderings of the subgoals.

context begin

Unified Memory Model (UMM)

11.1 More Word Lemmas

This is a holding area for Word utility lemmas that are too specific or unpolished for the AFP, but which are reusable enough to be collected together for the rest of L4V. New utility lemmas that only prove facts about words should be added here (in preference to being kept where they were first needed).

```

type-synonym field-name = string
type-synonym qualified-field-name = field-name list

```

```

type-synonym typ-name = string

```

A *typ-desc* wraps a *typ-struct* with a typ name. A *typ-struct* is either a Scalar, with size, alignment and either a field description (for *typ-info*) or a 'normalisor' (for *typ-uinfo*), or an Aggregate, with a list of *typ-desc*, field name, and field descriptor (for the complete sub-structure) or unit (for *typ-uinfo*). The field description for aggregates is an extension of the original work of H. Tuch. It is used to make the construction of a new structure from nested structures / arrays more efficient. Properties like commutation of fields can be expressed and proven for the toplevel fields only, without having to re-examine the nested leaves of the tree.

```

In order to construct a type of class *mem-type* we usually construct extended type-info for class *xmem-contained-type*. The extended type-info is better behaved with respect to composition of sub-structures / arrays.

using *is-scene-fold*[*of map m ms*] **by** (*simp add: list.pred-map comp-def fold-map*)

This expresses "disjointness" on scenes, saying that two scenes occupy disjoint parts of the type.

It is stronger than "commutativity" $\forall a c. m1 a (m2 a b) = m2 a (m1 a b)$ which is enough to show composition, but in our cases we are interested in disjointness. Important difference: a scene m "commutes" with itself, but only $\lambda a. id$ is disjoint with itself.

11.19 More properties of maps plus map disjunction.

```

theory MapExtra
imports Main
begin

```

BEWARE: we are not interested in using the $\text{dom } x \cap \text{dom } y = \{\}$ rules from Map for our separation logic proofs. As such, we overwrite the Map rules where that form of disjointness is in the assumption conflicts with a name we want to use with \perp .

A note on naming: Anything not involving heap disjunction can potentially be incorporated directly into Map.thy, thus uses m . Anything involving heap disjunction is not really mergeable with Map, is destined for use in separation logic, and hence uses h

by (*simp add: map-disj-def*)

11.22.1 Map associativity-commutativity based on map disjunction

lemma *map-add-com*:
 $h_0 \perp h_1 \implies h_0 ++ h_1 = h_1 ++ h_0$
by (*drule map-disjD, rule map-add-comm, force*)

lemma *map-add-left-commute*:
 $h_0 \perp h_1 \implies h_0 ++ (h_1 ++ h_2) = h_1 ++ (h_0 ++ h_2)$
by (*simp add: map-add-com map-disj-com*)

lemma *map-add-disj*:
 $h_0 \perp (h_1 ++ h_2) = (h_0 \perp h_1 \wedge h_0 \perp h_2)$
by (*simp add: map-disj-def, fast*)

lemma *map-add-disj'*:
 $(h_1 ++ h_2) \perp h_0 = (h_1 \perp h_0 \wedge h_2 \perp h_0)$
by (*simp add: map-disj-def, fast*)

We redefine $(++)$ associativity to bind to the right, which seems to be the more common case. Note that when a theory includes `Map` again, *map-add-assoc* will return to the simpset and will cause infinite loops if its symmetric counterpart is added (e.g. via *map-ac-simps*)

declare *map-add-assoc* [*simp del*]

Since the associativity-commutativity of $(++)$ relies on map disjunction, we include some basic rules into the ac set.

lemmas *map-ac-simps* =
 $map-add-assoc[symmetric]\ map-add-com\ map-disj-com$
 $map-add-left-commute\ map-add-disj\ map-add-disj'$

Like in Separation.thy, these arrows are defined using *bsub* and *esub* but have an *input* syntax abbreviation with just *sub*. Why? Because if *sub* is the only way, people write things like $p \mapsto^i (f x y) v$ instead of $p \mapsto^i (f x y) v$. We preserve the *sub* syntax though, because *esub* and *bsub* are a pain to type.

```

Derived from *array-assertion*, an appropriate assertion for performing a pointer addition, or for dereferencing a pointer addition (the strong case).

In either case, there must be an array connecting the two ends of the pointer transition, with the caveat that the last address can be just out of the array if the pointer is not dereferenced, thus the strong/weak distinction.

If the pointer doesn't actually move, nothing is learned.

```

11.26 Instantiation, inferring type instantiation from term instantiation.

```

ML-val
<
instantiate <'a=typ <nat> and x=term <1::nat> in term <x + x> for x::'a::plus>
>

```

This is a variant of of the instantiate antiquotation, e.g.: `\<^instantiate>\<open>'a=\<^typ>\<close> and x=\<^term>\<open>1::nat\<close> in term \<open>x + x\<close> for x::\<open>'a::plus\<close>\<close>.`

The instantiate antiquotation requires the explicit instantiation of type-

variables, including those that can be inferred from the term instantiation. This makes the code very explicit, predictable and efficient as no types have to be calculated at runtime or be 'guessed' by the reader. On the other hand it can make the resulting code quite verbose when the number of type variables increases.

In this theory we provide a variant, that allows to omit those type-instantiations that are already fixed by the given term instantiations. This follows the same idea as e.g. `Drule.infer_instantiate`.

Moreover, we provide a variant that also takes a morphism into account. The use-case here is that the instantiate expression is written within a locale context but later on is used in an interpretation of the locale (given by morphism phi). Before instantiation the term is exported (according to morphism phi).

```

in end;

end
>

```

Here an example with explicit instantiation.

```

ML-val <
val b = Free(n, typ <nat>)
val t1 = instantiate <'a = typ <nat> and a = <@{term 1::nat}> and b=<b>
    in term <a + b> for a b::'a::plus>
>

```

With the new variant the type instantiation can be omitted as it is already inferred from the term instantiations. Note that the result of the antiquotation is function that expects a `Proof.context`. This is used to perform the necessary type inference and provide context sensitive error messages.

```

ML-val <
val b = Free(n, typ <nat>)
val t1 = infer-instantiate <a = term <1::nat> and b=<b>
    in term <a + b> for a b::'a::plus> @<context>
>

```

This can be shortened:

```

ML-val <
val b = Free(n, typ <nat>)
val t1 = infer-instantiate <a = term <1::nat> and b=<b>
    in term <a + b>> @<context>
>

```

Here is an example where not all type variables can be inferred from the term instantiation. Those types can be explicitly instantiated.

```

ML-val <
val t1 = infer-instantiate <'b = typ <int> and a = <@{term 1::nat}>
    in term <Pair a> for a ::'a > @<context>
>

```

```

ML-val <
val t1 = morph-infer-instantiate <'b = typ <int> and a = <@{term 1::nat}>
    in term <Pair a> for a ::'a > Morphism.identity @<context>
>

```

```

ML-val <
val v = Proof-Context.read-term-pattern @<context> v
val t1 = infer-instantiate <'b = typ <int> and a = v
    in term <Pair a> for a ::'a > @<context>
>

```

```

ML-val <
val v = Proof-Context.read-term-pattern @<context> v::'a::type |> Thm.cterm-of
@<context>
val t1 = infer-instantiate <'b = ctyp <int> and a = v
    in cterm <Pair a> for a ::'a > @<context>
>

```

```

ML-val <
  val t1 = infer-instantiate <'b = ctyp <int> and a = <@{cterm 1::nat}>
    in cterm <Pair a> for a ::'a > @<context>
  >

```

```

context
  fixes x::'a::plus
begin
ML-val <
  val b = Free(n, typ <nat>)
  val t1 = infer-instantiate <a = <@{term 1::nat}> and b=<b>
    in term <a + b> for a b> @<context>
  >
end

```

Note that the antiquotation only makes some local type-inference on the term parameters alone. There might be further use cases to perform a type inference on the whole term instead. This might be further fine-tuned by inserting explicit dummy types to be inferred: -.

```

ML <
  fun infer-types-simple ctxt =
    singleton (Type-Infer-Context.infer-types ctxt) #>
    singleton (Type-Infer.fixate ctxt false);

  val b = Free(n, dummyT)
  val t1 = instantiate <'a = typ <-> and a = <@{term 1::nat}> and b=<b>
    in prop <a + b = a + b> for a b::'a::plus > |> infer-types-simple @<context>
  >

end

```

Note that the C-Parser associates sequential composition to the right. So the first statement is typically already an 'atomic' statement (or at least no further sequential composition) that can be solved. We place it as the second precondition because the *modifies*-tactic follows the canonical order of tactical reasoning and solves the subgoals from the back. So *c1* is already solved before further decomposing *c2*. This keeps the number of subgoals (and thus the overall goal-state) small.

We integrate `mlex` and `mlyacc` directly into Isabelle:

- We compile the SML files according to the description in `tools/mlyacc/src/FILES`
- We export the necessary signatures and structures to the Isabelle/ML environment.
- As `mlex` / `mlyacc` operate directly on files we invoke them on temporary files and redirect `stdout` / `stderr` to display the messages within PIDE. We wrap this in Isabelle commands `mlex`, `mlyacc`.
