

Bernoulli Numbers

Lukas Bulwahn and Manuel Eberl

May 21, 2019

Abstract

Bernoulli numbers were first discovered in the closed-form expansion of the sum $1^m + 2^m + \dots + n^m$ for a fixed m and appear in many other places. This entry provides three different definitions for them: a recursive one, an explicit one, and one through their exponential generating function.

In addition, we prove some basic facts, e. g. their relation to sums of powers of integers and that all odd Bernoulli numbers except the first are zero. We also prove the correctness of the Akiyama–Tanigawa algorithm [2] for computing Bernoulli numbers with reasonable efficiency, and we define the periodic Bernoulli polynomials (which appear e. g. in the Euler–MacLaurin summation formula and the expansion of the log-Gamma function) and prove their basic properties.

```

The “normal” Bernoulli numbers are the negative Bernoulli numbers B_n^- we just defined (so called because $B_1^- = -\frac{1}{2}$). There is also another convention, the positive Bernoulli numbers B_n^+ , which differ from the negative ones only in that $B_1^+ = \frac{1}{2}$. Both conventions have their justification, since a number of theorems are easier to state with one than the other.

Given the n -th Bernoulli polynomial $B_n(x)$, one can define the periodic function $P_n(x) = B_n(x - \lfloor x \rfloor)$, which shares many of the interesting properties of

the Bernoulli polynomials. In particular, all $P_n(x)$ with $n \neq 1$ are continuous and if $n \geq 3$, they are continuously differentiable with $P'_n(x) = nP_{n-1}(x)$ just like the Bernoulli polynomials themselves.

These functions occur e. g. in the Euler–MacLaurin summation formula and Stirling’s approximation for the logarithmic Gamma function.

Bernoulli

HOL-Computational-Algebra.Formal-Power-Series

HOL-Library.Stirling

begin

In the following, we will prove the correctness of the Akiyama–Tanigawa algorithm [2], which is a simple algorithm for computing Bernoulli numbers that was discovered by Akiyama and Tanigawa [1] essentially as a by-product of their studies of the Euler–Zagier multiple zeta function. The algorithm is based on a number triangle (similar to Pascal’s triangle) in which the Bernoulli numbers are the leftmost diagonal.

While the algorithm itself is quite simple, proving it correct is not entirely trivial. We will use generating functions and Stirling numbers, mostly following the presentation by Kaneko [2].

The following operator is a variant of the *fps-XD* operator where the multiplication is not with *fps-X*, but with an arbitrary formal power series. It is not quite clear if this operator has a less ad-hoc meaning than the fashion in which we use it; it is, however, very useful for proving the relationship between Stirling numbers and Bernoulli numbers.

context

includes *fps-notation*

<proof>

3.1 Generating function of Stirling numbers

lemma *Stirling-n-0*: $\text{Stirling } n 0 = (\text{if } n = 0 \text{ then } 1 \text{ else } 0)$
<proof>

The generating function of Stirling numbers w. r. t. their first argument:

$$\sum_{n=0}^{\infty} \left\{ \begin{matrix} n \\ m \end{matrix} \right\} \frac{x^n}{n!} = \frac{(e^x - 1)^m}{m!}$$

definition *Stirling-fps* :: $\text{nat} \Rightarrow \text{real } \text{fps}$ **where**
 $\text{Stirling-fps } m = \text{fps-const } (1 / \text{fact } m) * (\text{fps-exp } 1 - 1) ^ m$

theorem *sum-Stirling-binomial*:
 $\text{Stirling } (\text{Suc } n) (\text{Suc } m) = (\sum_{i=0..n} \text{Stirling } i m * \binom{n}{i})$

<proof>

lemma *Stirling-fps-aux*: $(\text{fps-exp } 1 - 1) \wedge m \ \$ n * \text{fact } n = \text{fact } m * \text{real } (\text{Stirling } n \ m)$

<proof>

lemma *Stirling-fps-nth*: $\text{Stirling-fps } m \ \$ n = \text{Stirling } n \ m / \text{fact } n$

<proof>

theorem *Stirling-fps-altdef*: $\text{Stirling-fps } m = \text{Abs-fps } (\lambda n. \text{Stirling } n \ m / \text{fact } n)$

<proof>

theorem *Stirling-closed-form*:

$\text{real } (\text{Stirling } n \ k) = (\sum_{j \leq k} (-1)^{\wedge(k-j)} * \text{real } (k \ \text{choose } j) * \text{real } j^{\wedge n}) / \text{fact } k$

<proof>

3.2 Generating function of Bernoulli numbers

We will show that the negative and positive Bernoulli numbers are the coefficients of the exponential generating function $\frac{x}{e^x-1}$ (resp. $\frac{x}{1-e^{-x}}$), i. e.

$$\sum_{n=0}^{\infty} B_n^- \frac{x^n}{n!} = \frac{x}{e^x - 1}$$

$$\sum_{n=0}^{\infty} B_n^+ \frac{x^n}{n!} = \frac{x}{1 - e^{-1}}$$

definition *bernoulli-fps* :: 'a :: real-normed-field fps

where *bernoulli-fps* = *fps-X* / (*fps-exp* 1 - 1)

definition *bernoulli'-fps* :: 'a :: real-normed-field fps

where *bernoulli'-fps* = *fps-X* / (1 - (*fps-exp* (-1)))

lemma *bernoulli-fps-altdef*: *bernoulli-fps* = *Abs-fps* ($\lambda n. \text{of-real } (\text{bernoulli } n) / \text{fact } n :: 'a$)

and *bernoulli-fps-aux*: $\text{bernoulli-fps} * (\text{fps-exp } 1 - 1 :: 'a :: \text{real-normed-field fps}) = \text{fps-X}$

<proof>

theorem *fps-nth-bernoulli-fps* [*simp*]:

$\text{fps-nth } \text{bernoulli-fps } n = \text{of-real } (\text{bernoulli } n) / \text{fact } n$

<proof>

lemma *bernoulli'-fps-aux*:

$(\text{fps-exp } 1 - 1) * \text{Abs-fps } (\lambda n. \text{of-real } (\text{bernoulli}' n) / \text{fact } n :: 'a) = \text{fps-exp } 1 * \text{fps-X}$

and *bernoulli'-fps-aux'*:

$(1 - \text{fps-exp } (-1)) * \text{Abs-fps } (\lambda n. \text{of-real } (\text{bernoulli}' n) / \text{fact } n :: 'a) = \text{fps-X}$

and *bernoulli'-fps-altdef*:
 $bernoulli'\text{-fps} = \text{Abs-fps } (\lambda n. \text{of-real } (bernoulli' n) / \text{fact } n :: 'a :: \text{real-normed-field})$
 $\langle \text{proof} \rangle$

theorem *fps-nth-bernoulli'-fps [simp]*:
 $fps\text{-nth } bernoulli'\text{-fps } n = \text{of-real } (bernoulli' n) / \text{fact } n$
 $\langle \text{proof} \rangle$

lemma *bernoulli-fps-conv-bernoulli'-fps*: $bernoulli\text{-fps} = bernoulli'\text{-fps} - \text{fps-X}$
 $\langle \text{proof} \rangle$

lemma *bernoulli'-fps-conv-bernoulli-fps*: $bernoulli'\text{-fps} = bernoulli\text{-fps} + \text{fps-X}$
 $\langle \text{proof} \rangle$

theorem *bernoulli-odd-eq-0*:
assumes $n \neq 1$ **and** *odd* n
shows $bernoulli n = 0$
 $\langle \text{proof} \rangle$

lemma *bernoulli'-odd-eq-0*: $n \neq 1 \implies \text{odd } n \implies bernoulli' n = 0$
 $\langle \text{proof} \rangle$

The following simplification rule takes care of rewriting *bernoulli* n to 0 for any odd numeric constant greater than 1:

lemma *bernoulli-odd-numeral-eq-0 [simp]*: $bernoulli (\text{numeral } (\text{Num.Bit1 } n)) = 0$
 $\langle \text{proof} \rangle$

lemma *bernoulli'-odd-numeral-eq-0 [simp]*: $bernoulli' (\text{numeral } (\text{Num.Bit1 } n)) = 0$
 $\langle \text{proof} \rangle$

The following explicit formula for Bernoulli numbers can also be derived reasonably easily using the generating functions of Stirling numbers and Bernoulli numbers. The proof follows an answer by Marko Riedel on the Mathematics StackExchange [3].

theorem *bernoulli-altdef*:
 $bernoulli n = (\sum_{m \leq n} \sum_{k \leq m} (-1)^k * \text{real } (m \text{ choose } k) * \text{real } k^n / \text{real } (Suc m))$
 $\langle \text{proof} \rangle$

3.3 Akiyama–Tanigawa algorithm

First, we define the Akiyama–Tanigawa number triangle as shown by Kaneko [2]. We define this generically, parametrised by the first row. This makes the proofs a little bit more modular.

fun *gen-akiyama-tanigawa* :: $(\text{nat} \Rightarrow \text{real}) \Rightarrow \text{nat} \Rightarrow \text{nat} \Rightarrow \text{real}$ **where**

$gen\text{-}akiyama\text{-}tanigawa\ f\ 0\ m = f\ m$
 $| gen\text{-}akiyama\text{-}tanigawa\ f\ (Suc\ n)\ m =$
 $real\ (Suc\ m) * (gen\text{-}akiyama\text{-}tanigawa\ f\ n\ m - gen\text{-}akiyama\text{-}tanigawa\ f\ n\ (Suc\ m))$

lemma *gen-akiyama-tanigawa-0* [simp]: $gen\text{-}akiyama\text{-}tanigawa\ f\ 0 = f$
 $\langle proof \rangle$

The “regular” Akiyama–Tanigawa triangle is the one that is used for reading off Bernoulli numbers:

definition *akiyama-tanigawa* **where**

$akiyama\text{-}tanigawa = gen\text{-}akiyama\text{-}tanigawa\ (\lambda n. 1 / real\ (Suc\ n))$

context
begin

private definition *AT-fps* :: $(nat \Rightarrow real) \Rightarrow nat \Rightarrow real\ fps$ **where**

$AT\text{-}fps\ f\ n = (fps\text{-}X - 1) * Abs\text{-}fps\ (gen\text{-}akiyama\text{-}tanigawa\ f\ n)$

private lemma *AT-fps-Suc*: $AT\text{-}fps\ f\ (Suc\ n) = (fps\text{-}X - 1) * fps\text{-}deriv\ (AT\text{-}fps\ f\ n)$

$\langle proof \rangle$ **lemma** *AT-fps-altdef*:

$AT\text{-}fps\ f\ n =$

$(\sum_{m \leq n}. fps\text{-}const\ (real\ (Stirling\ n\ m)) * (fps\text{-}X - 1) ^ m * (fps\text{-}deriv\ ^ m\ (AT\text{-}fps\ f\ 0))$

$\langle proof \rangle$ **lemma** *AT-fps-0-nth*: $AT\text{-}fps\ f\ 0\ \$\ n = (if\ n = 0\ then\ -f\ 0\ else\ f\ (n - 1) - f\ n)$

$\langle proof \rangle$

The following fact corresponds to Proposition 1 in Kaneko’s proof:

lemma *gen-akiyama-tanigawa-n-0*:

$gen\text{-}akiyama\text{-}tanigawa\ f\ n\ 0 =$

$(\sum_{k \leq n}. (-1) ^ k * fact\ k * real\ (Stirling\ (Suc\ n)\ (Suc\ k)) * f\ k)$

$\langle proof \rangle$

The following lemma states that for $A(x) := \sum_{k=0}^{\infty} a_{0,k} x^k$, we have

$$\sum_{n=0}^{\infty} a_{n,0} \frac{x^n}{n!} = e^x A(1 - e^x)$$

which correspond’s to Kaneko’s remark at the end of Section 2. This seems to be easier to formalise than his actual proof of his Theorem 1, since his proof contains an infinite sum of formal power series, and it was unclear to us how to capture this formally.

lemma *gen-akiyama-tanigawa-fps*:

$Abs\text{-}fps\ (\lambda n. gen\text{-}akiyama\text{-}tanigawa\ f\ n\ 0 / fact\ n) = fps\text{-}exp\ 1 * fps\text{-}compose\ (Abs\text{-}fps\ f)\ (1 - fps\text{-}exp\ 1)$

$\langle proof \rangle$

As Kaneko notes in his afore-mentioned remark, if we let $a_{0,k} = \frac{1}{k+1}$, we obtain

$$A(z) = \sum_{k=0}^{\infty} \frac{x^k}{k+1} = -\frac{\ln(1-x)}{x}$$

and therefore

$$\sum_{n=0}^{\infty} a_{n,0} \frac{x^n}{n!} = \frac{xe^x}{e^x - 1} = \frac{x}{1 - e^{-x}},$$

which immediately gives us the connection to the positive Bernoulli numbers.

3.4 Efficient code

We can now compute parts of the Akiyama–Tanigawa (and thereby Bernoulli numbers) with reasonable efficiency but iterating the recurrence row by row. We essentially start with some finite prefix of the zeroth row, say of length n , and then apply the recurrence one to get a prefix of the first row of length $n - 1$ etc.

The analytic continuation of the exponential generating function of the Bernoulli numbers is $\frac{z}{e^z-1}$, which has simple poles at all $2ki\pi$ for $k \in \mathbb{Z} \setminus \{0\}$. We will need the residue at these poles:

```

lemma residue-bernoulli:
  assumes n  $\neq$  0
  shows residue ( $\lambda z. 1 / (z ^ m * (exp z - 1))$ ) (2 * pi * real-of-int n * i) =
    1 / (2 * pi * real-of-int n * i) ^ m
⟨proof⟩

```

At positive integers greater than 1, the Riemann zeta function is simply the infinite sum $\zeta(n) = \sum_{k=1}^{\infty} k^{-n}$. For even n , this quantity can also be expressed in terms of Bernoulli numbers.

To show this, we employ a similar strategy as in the meromorphic asymptotics approach: We apply the Residue Theorem to the exponential generating function of the Bernoulli numbers:

$$\sum_{n=0}^{\infty} \frac{B_n}{n!} z^n = \frac{z}{e^z - 1}$$

Recall that this function has poles at $2ki\pi$ for $k \in \mathbb{Z} \setminus \{0\}$. In the meromorphic asymptotics case, we integrated along a circle of radius $3i\pi$ in order to get the dominant singularities $2i\pi$ and $-2i\pi$. Now, however, we will not use a fixed integration path, but we let the integration path become bigger and bigger. Because the integrand decays relatively quickly if $n > 1$, the integral vanishes in the limit and we obtain not just an asymptotic formula, but an exact representation of B_n as an infinite sum.

For odd n , we have $B_n = 0$, but for even n , the residues at $2ki\pi$ and $-2ki\pi$ combine nicely to $2 \cdot (-2k\pi)^{-n}$, and after some simplification we get the formula for B_n .

Another difference to the meromorphic asymptotics is that we now use a rectangle instead of a circle as the integration path. For the asymptotics, only a big-oh bound was needed for the integral over one fixed integration path, and the circular path was very convenient. However, now we need to explicitly bound the integral for a whole sequence of integration paths that grow in size, and bounding $e^z - 1$ for z on a circle is very tedious. On a rectangle, this term can be bounded much more easily. Still, we have to do this separately for all four edges of the rectangle, which will be a bit tedious.

theorem *nat-even-power-sums-complex:*

assumes $n': n' > 0$

shows $(\lambda k. 1 / \text{of-nat } (\text{Suc } k) \wedge (2*n')) :: \text{complex sums}$

$\text{of-real } ((-1) \wedge \text{Suc } n' * \text{bernoulli } (2*n') * (2 * \text{pi}) \wedge (2 * n') / (2 * \text{fact } (2*n'))))$

<proof>

corollary *nat-even-power-sums-real:*

assumes $n': n' > 0$

shows $(\lambda k. 1 / \text{real } (\text{Suc } k) \wedge (2*n')) \text{ sums}$

$((-1) \wedge \text{Suc } n' * \text{bernoulli } (2*n') * (2 * \text{pi}) \wedge (2 * n') / (2 * \text{fact } (2*n'))))$

(is ?f sums ?L)

<proof>

We can now also easily determine the signs of Bernoulli numbers: the above formula clearly shows that the signs of B_{2n} alternate as n increases, and we

already know that $B_{2n+1} = 0$ for any positive n . A lot of other facts about the signs of Bernoulli numbers follow.

corollary *sgn-bernoulli-even:*

assumes $n > 0$

shows $\text{sgn}(\text{bernoulli}(2 * n)) = (-1)^{\text{Suc } n}$

<proof>

corollary *bernoulli-even-nonzero:* $\text{even } n \implies \text{bernoulli } n \neq 0$

<proof>

corollary *sgn-bernoulli:*

$\text{sgn}(\text{bernoulli } n) =$

(if $n = 0$ then 1 else if $n = 1$ then -1 else if odd n then 0 else $(-1)^{\text{Suc } (n \text{ div } 2)}$)

<proof>

corollary *bernoulli-zero-iff:* $\text{bernoulli } n = 0 \iff \text{odd } n \wedge n \neq 1$

<proof>

corollary *bernoulli'-zero-iff:* $(\text{bernoulli}' n = 0) \iff (n \neq 1 \wedge \text{odd } n)$

<proof>

corollary *bernoulli-pos-iff:* $\text{bernoulli } n > 0 \iff n = 0 \vee n \bmod 4 = 2$

<proof>

corollary *bernoulli-neg-iff:* $\text{bernoulli } n < 0 \iff n = 1 \vee n > 0 \wedge 4 \text{ dvd } n$

<proof>

We also get the solution of the Basel problem (the sum over all squares of positive integers) and any ‘Basel-like’ problem with even exponent. The case of odd exponents is much more complicated and no similarly nice closed form is known for these.

corollary *nat-squares-sums:* $(\lambda n. 1 / (n+1)^2) \text{ sums } (\text{pi}^2 / 6)$

<proof>

corollary *nat-power4-sums:* $(\lambda n. 1 / (n+1)^4) \text{ sums } (\text{pi}^4 / 90)$

<proof>

corollary *nat-power6-sums:* $(\lambda n. 1 / (n+1)^6) \text{ sums } (\text{pi}^6 / 945)$

<proof>

corollary *nat-power8-sums:* $(\lambda n. 1 / (n+1)^8) \text{ sums } (\text{pi}^8 / 9450)$

<proof>

end
