Formalization of Randomized Approximation Algorithms for Frequency Moments

Emin Karayel

March 29, 2023

Abstract

In 1999 Alon et. al. introduced the still active research topic of approximating the frequency moments of a data stream using randomized algorithms with minimal space usage. This includes the problem of estimating the cardinality of the stream elements—the zeroth frequency moment. But, also higher-order frequency moments that provide information about the skew of the data stream. (The k-th frequency moment of a data stream is the sum of the k-th powers of the occurrence counts of each element in the stream.) This entry formalizes three randomized algorithms for the approximation of F_0, F_2 and F_k for $k \geq 3$ based on [1, 2] and verifies their expected accuracy, success probability and space usage.

shows *card S* > *1*
⟨*proof*⟩

lemma *count-list-ge-2-iff*:
assumes *y* < *z*
assumes *z* < *length xs*
assumes *xs* ! *y* = *xs* ! *z*
shows *count-list xs* (*xs* ! *y*) > *1*
⟨*proof*⟩

Results about multisets and sorting

This is a induction scheme over the distinct elements of a multisets: We can represent each multiset as a sum like: *replicate-mset* n_1 x_1 + *replicate-mset* n_2 x_2 + ... + *replicate-mset* n_k x_k where the x_i are distinct.

lemma *disj-induct-mset*:
assumes *P* {#}
assumes ⋀*n M x*. *P M* ⟹ ¬(*x* ∈# *M*) ⟹ *n* > *0* ⟹ *P* (*M* + *replicate-mset n x*)
shows *P M*
⟨*proof*⟩

lemma *prod-mset-conv*:
fixes *f* :: *'a* ⇒ *'b*::{*comm-monoid-mult*}
shows *prod-mset* (*image-mset f A*) = *prod* (λ*x*. *f x*^(*count A x*)) (*set-mset A*)
⟨*proof*⟩

There is a version *sum-list-map-eq-sum-count* but it doesn't work if the function maps into the reals.

lemma *sum-list-eval*:
fixes *f* :: *'a* ⇒ *'b*::{*ring*,*semiring-1*}
shows *sum-list* (*map f xs*) = (∑ *x* ∈ *set xs*. *of-nat* (*count-list xs x*) ∗ *f x*)
⟨*proof*⟩

lemma *prod-list-eval*:
fixes *f* :: *'a* ⇒ *'b*::{*ring*,*semiring-1*,*comm-monoid-mult*}
shows *prod-list* (*map f xs*) = (∏ *x* ∈ *set xs*. (*f x*)^(*count-list xs x*))
⟨*proof*⟩

lemma *sorted-sorted-list-of-multiset*: *sorted* (*sorted-list-of-multiset M*)
⟨*proof*⟩

lemma *count-mset*: *count* (*mset xs*) *a* = *count-list xs a*
⟨*proof*⟩

lemma *swap-filter-image*: *filter-mset g* (*image-mset f A*) = *image-mset f* (*filter-mset* (*g* ∘ *f*) *A*)
⟨*proof*⟩

⟨*proof*⟩

Results about rounding and floating point numbers

lemma *round-down-ge*:
x ≤ *round-down prec x* + *2 powr* (−*prec*)
⟨*proof*⟩

lemma *truncate-down-ge*:
x ≤ *truncate-down prec x* + *abs x* ∗ *2 powr* (−*prec*)
⟨*proof*⟩

lemma *truncate-down-pos*:
assumes *x* ≥ *0*
shows *x* ∗ (*1* − *2 powr* (−*prec*)) ≤ *truncate-down prec x*
⟨*proof*⟩

lemma *truncate-down-eq*:
assumes *truncate-down r x* = *truncate-down r y*
shows *abs* (*x*−*y*) ≤ *max* (*abs x*) (*abs y*) ∗ *2 powr* (−*real r*)
⟨*proof*⟩

definition *rat-of-float* :: *float* ⇒ *rat* **where**
rat-of-float f = *of-int* (*mantissa f*) ∗
(*if exponent f* ≥ *0 then 2* ^ (*nat* (*exponent f*)) *else 1* / *2* ^ (*nat* (−*exponent f*)))

lemma *real-of-rat-of-float*: *real-of-rat* (*rat-of-float x*) = *real-of-float x*
⟨*proof*⟩

lemma *log-est*: *log 2* (*real n* + *1*) ≤ *n*

⟨*proof*⟩

lemma *truncate-mantissa-bound*:
abs (⌊*x* ∗ *2 powr* (*real r* − *real-of-int* ⌊*log 2* |*x*|⌋)⌋) ≤ *2* ^ (*r*+*1*) (**is** *?lhs* ≤ -)
⟨*proof*⟩

lemma *truncate-float-bit-count*:
bit-count (*F*$_e$ (*float-of* (*truncate-down r x*))) ≤ *10* + *4* ∗ *real r* + *2*∗*log 2* (*2* + |*log 2* |*x*||)
(**is** *?lhs* ≤ *?rhs*)
⟨*proof*⟩

definition *prime-above* :: *nat* ⇒ *nat*
where *prime-above n* = (*SOME x*. *x* ∈ {*n*..(*2*∗*n*+*2*)} ∧ *prime x*)

The term *prime-above n* returns a prime between *n* and *2* ∗ *n* + *2*. Because of Bertrand's postulate there always is such a value. In a refinement of the algorithms, it may make sense to replace this with an algorithm, that finds such a prime exactly or approximately.

The definition is intentionally inexact, to allow refinement with various algorithms, without modifying the high-level mathematical correctness proof.

lemma *ex-subset*:
assumes ∃ *x* ∈ *A*. *P x*
assumes *A* ⊆ *B*
shows ∃ *x* ∈ *B*. *P x*
⟨*proof*⟩

lemma
shows *prime-above-prime*: *prime* (*prime-above n*)
and *prime-above-range*: *prime-above n* ∈ {*n*..(*2*∗*n*+*2*)}
⟨*proof*⟩

lemma *prime-above-min*: *prime-above n* ≥ *2*
⟨*proof*⟩

lemma *prime-above-lower-bound*: *prime-above n* ≥ *n*
⟨*proof*⟩

lemma *prime-above-upper-bound*: *prime-above n* ≤ *2*∗*n*+*2*
⟨*proof*⟩

end

begin

This section contains a formalization of a new algorithm for the zero-th frequency moment inspired by ideas described in [2]. It is a KMV-type (k-minimum value) algorithm with a rounding method and matches the space complexity of the best algorithm described in [2].

In addition to the Isabelle proof here, there is also an informal hand-written proof in Appendix A.

A Informal proof of correctness for the F_0 algorithm

This appendix contains a detailed informal proof for the new Rounding-KMV algorithm that approximates F_0 introduced in Section 7 for reference. It follows the same reasoning as the formalized proof.

Because of the amplification result about medians (see for example [1, §2.1]) it is enough to show that each of the estimates the median is taken from is within the desired interval with success probability $\frac{2}{3}$. To verify the latter, let $a_1, \ldots, a_m$ be the stream elements, where we assume that the elements are a subset of $\{0, \ldots, n-1\}$ and $0 < \delta < 1$ be the desired relative accuracy. Let p be the smallest prime such that $p \geq \max(n, 19)$ and let h be a random polynomial over $GF(p)$ with degree strictly less than 2. The algoritm also introduces the internal parameters t, r defined by:

$$t := \lceil 80\delta^{-2} \rceil \qquad\qquad r := 4 \log_2 \lceil \delta^{-1} \rceil + 23$$

The estimate the algorithm obtains is R, defined using:

$$H := \{ \lfloor h(a) \rfloor_r | a \in A \} \qquad R := \begin{cases} tp \, (\min_t(H))^{-1} & \text{if } |H| \geq t \\ |H| & \text{othewise,} \end{cases}$$

where $A := \{a_1, \ldots, a_m\}$, $\min_t(H)$ denotes the t-th smallest element of H and $\lfloor x \rfloor_r$ denotes the largest binary floating point number smaller or equal to x with a mantissa that requires at most r bits to represent.[1] With these definitions, it is possible to state the main theorem as:

$$P(|R - F_0| \leq \delta |F_0|) \geq \frac{2}{3}.$$

which is shown separately in the following two subsections for the cases $F_0 \geq t$ and $F_0 < t$.

[1] This rounding operation is called *truncate-down* in Isabelle, it is defined in HOL-Library.Float.

A.1 Case $F_0 \geq t$

Let us introduce:

$$H^* := \{h(a) | a \in A\}^{\#} \qquad R^* := tp\left(\min_t^{\#}(H^*)\right)^{-1}$$

These definitions are modified versions of the definitions for H and R: The set H^* is a multiset, this means that each element also has a multiplicity, counting the number of *distinct* elements of A being mapped by h to the same value. Note that by definition: $|H^*| = |A|$. Similarly the operation $\min_t^{\#}$ obtains the t-th element of the multiset H (taking multiplicities into account). Note also that there is no rounding operation $\lfloor\cdot\rfloor_r$ in the definition of H^*. The key reason for the introduction of these alternative versions of H, R is that it is easier to show probabilistic bounds on the distances $|R^* - F_0|$ and $|R^* - R|$ as opposed to $|R - F_0|$ directly. In particular the plan is to show:

$$P\left(|R^* - F_0| > \delta' F_0\right) \leq \frac{2}{9}, \text{ and} \tag{1}$$

$$P\left(|R^* - F_0| \leq \delta' F_0 \wedge |R - R^*| > \frac{\delta}{4} F_0\right) \leq \frac{1}{9} \tag{2}$$

where $\delta' := \frac{3}{4}\delta$. I.e. the probability that R^* has not the relative accuracy of $\frac{3}{4}\delta$ is less that $\frac{2}{9}$ and the probability that assuming R^* has the relative accuracy of $\frac{3}{4}\delta$ but that R deviates by more that $\frac{1}{4}\delta F_0$ is at most $\frac{1}{9}$. Hence, the probability that neither of these events happen is at least $\frac{2}{3}$ but in that case:

$$|R - F_0| \leq |R - R^*| + |R^* - F_0| \leq \frac{\delta}{4} F_0 + \frac{3\delta}{4} F_0 = \delta F_0. \tag{3}$$

Thus we only need to show Equation 1 and 2. For the verification of Equation 1 let

$$Q(u) = |\{h(a) < u \mid a \in A\}|$$

and observe that $\min_t^{\#}(H^*) < u$ if $Q(u) \geq t$ and $\min_t^{\#}(H^*) \geq v$ if $Q(v) \leq t - 1$. To see why this is true note that, if at least t elements of A are mapped by h below a certain value, then the t-smallest element must also be within them, and thus also be below that value. And that the opposite direction of this conclusion is also true. Note that this relies on the fact that H^* is a multiset and that multiplicities are being taken into account, when computing the t-th smallest element. Alternatively, it is also possible to write $Q(u) = \sum_{a \in A} 1_{\{h(a) < u\}}$[2], i.e., Q is a sum of pairwise independent $\{0, 1\}$-valued random variables, with expectation $\frac{u}{p}$ and variance $\frac{u}{p} - \frac{u^2}{p^2}$.

[2]The notation 1_A is shorthand for the indicator function of A, i.e., $1_A(x) = 1$ if $x \in A$ and 0 otherwise.

[3] Using lineariy of expectation and Bienaymé's identity, it follows that $\operatorname{Var} Q(u) \leq \mathrm{E}\, Q(u) = |A| u p^{-1} = F_0 u p^{-1}$ for $u \in \{0, \ldots, p\}$.
For $v = \left\lfloor \frac{tp}{(1-\delta')F_0} \right\rfloor$ it is possible to conclude:

$$t - 1 \leq {}^{[4]} \frac{t}{(1-\delta')} - 3\sqrt{\frac{t}{(1-\delta')}} - 1 \leq \frac{F_0 v}{p} - 3\sqrt{\frac{F_0 v}{p}} \leq \mathrm{E}Q(v) - 3\sqrt{\mathrm{Var}Q(v)}$$

and thus using Tchebyshev's inequality:

$$\begin{aligned} P\left(R^* < \left(1-\delta'\right) F_0\right) &= P\left(\mathrm{rank}_t^{\#}(H^*) > \frac{tp}{(1-\delta')F_0}\right) \\ &\leq P(\mathrm{rank}_t^{\#}(H^*) \geq v) = P(Q(v) \leq t-1) \\ &\leq P\left(Q(v) \leq \mathrm{E}Q(v) - 3\sqrt{\mathrm{Var}Q(v)}\right) \leq \frac{1}{9}. \end{aligned} \tag{4}$$

Similarly for $u = \left\lceil \frac{tp}{(1+\delta')F_0} \right\rceil$ it is possible to conclude:

$$t \geq \frac{t}{(1+\delta')} + 3\sqrt{\frac{t}{(1+\delta')} + 1} + 1 \geq \frac{F_0 u}{p} + 3\sqrt{\frac{F_0 u}{p}} \geq \mathrm{E}Q(u) + 3\sqrt{\mathrm{Var}Q(v)}$$

and thus using Tchebyshev's inequality:

$$\begin{aligned} P\left(R^* > \left(1+\delta'\right) F_0\right) &= P\left(\mathrm{rank}_t^{\#}(H^*) < \frac{tp}{(1+\delta')F_0}\right) \\ &\leq P(\mathrm{rank}_t^{\#}(H^*) < u) = P(Q(u) \geq t) \\ &\leq P\left(Q(u) \geq \mathrm{E}Q(u) + 3\sqrt{\mathrm{Var}Q(u)}\right) \leq \frac{1}{9}. \end{aligned} \tag{5}$$

Note that Equation 4 and 5 confirm Equation 1. To verfiy Equation 2, note that

$$\min_t(H) = \lfloor \min_t^{\#}(H^*) \rfloor_r \tag{6}$$

if there are no collisions, induced by the application of $\lfloor h(\cdot) \rfloor_r$ on the elements of A. Even more carefully, note that the equation would remain true, as long as there are no collision within the smallest t elements of H^*. Because Equation 2 needs to be shown only in the case where $R^* \geq (1-\delta')F_0$, i.e., when $\min_t^{\#}(H^*) \leq v$, it is enough to bound the probability of a collision in the range $[0; v]$. Moreover Equation 6 implies $|\min_t(H) - \min_t^{\#}(H^*)| \leq \max(\min_t^{\#}(H^*), \min_t(H)) 2^{-r}$ from which it is possible to derive $|R^* - R| \leq \frac{\delta}{4} F_0$. Another important fact is that h is injective with probability $1 - \frac{1}{p}$,

[3] A consequence of h being chosen uniformly from a 2-independent hash family.
[4] The verification of this inequality is a lengthy but straightforward calculcation using the definition of δ' and t.

this is because h is chosen uniformly from the polynomials of degree less than 2. If it is a degree 1 polynomial it is a linear function on $GF(p)$ and thus injective. Because $p \geq 18$ the probability that h is not injective can be bounded by $1/18$. With these in mind, we can conclude:

$$
\begin{aligned}
& P\left(|R^* - F_0| \leq \delta' F_0 \wedge |R - R^*| > \frac{\delta}{4} F_0\right) \\
\leq\ & P\left(R^* \geq (1-\delta')F_0 \wedge \min_t^{\#}(H^*) \neq \min_t(H) \wedge h \text{ inj.}\right) + P(\neg h \text{ inj.}) \\
\leq\ & P\left(\exists a \neq b \in A. \lfloor h(a) \rfloor_r = \lfloor h(b) \rfloor_r \leq v \wedge h(a) \neq h(b)\right) + \frac{1}{18} \\
\leq\ & \frac{1}{18} + \sum_{a \neq b \in A} P\left(\lfloor h(a) \rfloor_r = \lfloor h(b) \rfloor_r \leq v \wedge h(a) \neq h(b)\right) \\
\leq\ & \frac{1}{18} + \sum_{a \neq b \in A} P\left(|h(a) - h(b)| \leq v 2^{-r} \wedge h(a) \leq v(1+2^{-r}) \wedge h(a) \neq h(b)\right) \\
\leq\ & \frac{1}{18} + \sum_{a \neq b \in A} \sum_{\substack{a', b' \in \{0,\ldots,p-1\} \wedge a' \neq b' \\ |a'-b'| \leq v 2^{-r} \wedge a' \leq v(1+2^{-r})}} P(h(a) = a') P(h(b) = b') \\
\leq\ & \frac{1}{18} + \frac{5 F_0^2 v^2}{2p^2} 2^{-r} \leq \frac{1}{9}.
\end{aligned}
$$

which shows that Equation 2 is true.

A.2 Case $F_0 < t$

Note that in this case $|H| \leq F_0 < t$ and thus $R = |H|$, hence the goal is to show that: $P(|H| \neq F_0) \leq \frac{1}{3}$. The latter can only happen, if there is a collision induced by the application of $\lfloor h(\cdot) \rfloor_r$. As before h is not injective

with probability at most $\frac{1}{18}$, hence:

$$\begin{aligned}
& P\left(|R - F_0| > \delta F_0\right) \leq P\left(R \neq F_0\right) \\
\leq\ & \frac{1}{18} + P\left(R \neq F_0 \wedge h \text{ inj.}\right) \\
\leq\ & \frac{1}{18} + P\left(\exists a \neq b \in A. \lfloor h(a) \rfloor_r = \lfloor h(b) \rfloor_r \wedge h \text{ inj.}\right) \\
\leq\ & \frac{1}{18} + \sum_{a \neq b \in A} P\left(\lfloor h(a) \rfloor_r = \lfloor h(b) \rfloor_r \wedge h(a) \neq h(b)\right) \\
\leq\ & \frac{1}{18} + \sum_{a \neq b \in A} P\left(|h(a) - h(b)| \leq p2^{-r} \wedge h(a) \neq h(b)\right) \\
\leq\ & \frac{1}{18} + \sum_{a \neq b \in A} \sum_{\substack{a', b' \in \{0, \ldots, p-1\} \\ a' \neq b' \wedge |a' - b'| \leq p2^{-r}}} P(h(a) = a') P(h(b) = b') \\
\leq\ & \frac{1}{18} + F_0^2 2^{-r+1} \leq \frac{1}{18} + t^2 2^{-r+1} \leq \frac{1}{9}.
\end{aligned}$$

Which concludes the proof. □
