

# International Mathematical Olympiad 2019

Manuel Eberl

November 24, 2021

## Abstract

This entry contains formalisations of the answers to three of the six problems of the International Mathematical Olympiad 2019, namely Q1, Q4, and Q5. The reason why these problems were chosen is that they are particularly amenable to formalisation: they can be solved with minimal use of libraries. The remaining three concern geometry and graph theory, which, in the author's opinion, are more difficult to formalise resp. require a more complex library.

## 1 Q1

**theory** *IMO2019-Q1*

**imports** *Main*

**begin**

Consider a function  $f : \mathbb{Z} \rightarrow \mathbb{Z}$  that fulfils the functional equation  $f(2a) + 2f(b) = f(f(a+b))$  for all  $a, b \in \mathbb{Z}$ .

Then  $f$  is either identically 0 or of the form  $f(x) = 2x + c$  for some constant  $c \in \mathbb{Z}$ .

**context**

**fixes**  $f :: int \Rightarrow int$  **and**  $m :: int$

**assumes**  $f\text{-eq}: f (2 * a) + 2 * f b = f (f (a + b))$

**defines**  $m \equiv (f 0 - f (-2)) \text{ div } 2$

**begin**

We first show that  $f$  is affine with slope  $(f(0) - f(-2)) / 2$ . This follows from plugging in  $(0, b)$  and  $(-1, b + 1)$  into the functional equation.

**lemma**  $f\text{-eq}'$ :  $f x = m * x + f 0$

*<proof>*

This version is better for the simplifier because it prevents it from looping.

**lemma**  $f\text{-eq}'\text{-aux}$  [*simp*]:  $NO\text{-MATCH } 0 x \Longrightarrow f x = m * x + f 0$

*<proof>*

Plugging in  $(0, 0)$  and  $(0, 1)$ .

**lemma**  $f\text{-classification}$ :  $(\forall x. f x = 0) \vee (\forall x. f x = 2 * x + f 0)$

*<proof>*

**end**

It is now easy to derive the full characterisation of the functions we considered:

**theorem**

**fixes**  $f :: int \Rightarrow int$

**shows**  $(\forall a b. f (2 * a) + 2 * f b = f (f (a + b))) \longleftrightarrow$

$(\forall x. f x = 0) \vee (\forall x. f x = 2 * x + f 0)$  (**is** *?lhs*  $\longleftrightarrow$  *?rhs*)

*<proof>*

**end**

## 2 Q4

**theory** *IMO2019-Q4*

**imports** *Prime-Distribution-Elementary.More-Dirichlet-Misc*

**begin**

Find all pairs  $(k, n)$  of positive integers such that  $k! = \prod_{i=0}^{n-1} (2^n - 2^i)$ .

## 2.1 Auxiliary facts

**lemma** *Sigma-insert*:  $\text{Sigma } (\text{insert } x \ A) \ f = (\lambda y. (x, y)) \ 'f \ x \cup \ \text{Sigma } \ A \ f$   
<proof>

**lemma** *atLeastAtMost-nat-numeral*:

$\{(m::\text{nat}).. \text{numeral } k\} =$   
(if  $m \leq \text{numeral } k$  then  $\text{insert } (\text{numeral } k) \ \{m.. \text{pred-numeral } k\}$  else  $\{\}$ )  
<proof>

**lemma** *greaterThanAtMost-nat-numeral*:

$\{(m::\text{nat}) < .. \text{numeral } k\} =$   
(if  $m < \text{numeral } k$  then  $\text{insert } (\text{numeral } k) \ \{m < .. \text{pred-numeral } k\}$  else  $\{\}$ )  
<proof>

**lemma** *fact-ge-power*:

**fixes**  $c :: \text{nat}$   
**assumes**  $\text{fact } n0 \geq c \wedge n0 \ c \leq n0 + 1$   
**assumes**  $n \geq n0$   
**shows**  $\text{fact } n \geq c \wedge n$   
<proof>

**lemma** *prime-multiplicity-prime*:

**fixes**  $p \ q :: 'a :: \text{factorial-semiring}$   
**assumes**  $\text{prime } p \ \text{prime } q$   
**shows**  $\text{multiplicity } p \ q = (\text{if } p = q \ \text{then } 1 \ \text{else } 0)$   
<proof>

We use Legendre's identity from the library. One could easily prove the property in question without the library, but it probably still saves a few lines.

*legendre-aux* (related to Legendre's identity) is the multiplicity of a given prime in the prime factorisation of  $n!$ .

**lemma** *multiplicity-prime-fact*:

**fixes**  $p :: \text{nat}$   
**assumes**  $\text{prime } p$   
**shows**  $\text{multiplicity } p \ (\text{fact } n) = \text{legendre-aux } n \ p$   
<proof>

The following are simple and trivial lower and upper bounds for *legendre-aux*:

**lemma** *legendre-aux-ge*:

**assumes**  $\text{prime } p \ k \geq 1$   
**shows**  $\text{legendre-aux } k \ p \geq \text{nat } \lfloor k / p \rfloor$   
<proof>

**lemma** *legendre-aux-less*:

**assumes**  $\text{prime } p \ k \geq 1$   
**shows**  $\text{legendre-aux } k \ p < k / (p - 1)$

*<proof>*

## 2.2 Main result

Now we move on to the main result: We fix two numbers  $n$  and  $k$  with the property in question and derive facts from that.

The triangle number  $T = n(n+1)/2$  is of particular importance here, so we introduce an abbreviation for it.

**context**

```
fixes  $k\ n :: \text{nat}$  and  $rhs\ T :: \text{nat}$   
defines  $rhs \equiv (\prod_{i < n}. 2^{\wedge n} - 2^{\wedge i})$   
defines  $T \equiv (n * (n - 1)) \text{ div } 2$   
assumes  $pos: k > 0\ n > 0$   
assumes  $k-n: \text{fact } k = rhs$ 
```

**begin**

We can rewrite the right-hand side into a more convenient form:

**lemma**  $rhs\text{-altdef}: rhs = 2^{\wedge T} * (\prod_{i=1..n}. 2^{\wedge i} - 1)$

*<proof>*

The multiplicity of 2 in the prime factorisation of the right-hand side is precisely  $T$ .

**lemma**  $multiplicity\text{-}2\text{-}rhs$  [*simp*]:  $multiplicity\ 2\ rhs = T$

*<proof>*

From Legendre's identities and the associated bounds, it can easily be seen that  $\lfloor k/2 \rfloor \leq T < k$ :

**lemma**  $k\text{-gt-}T: k > T$

*<proof>*

**lemma**  $T\text{-ge-half-}k: T \geq k \text{ div } 2$

*<proof>*

It can also be seen fairly easily that the right-hand side is strictly smaller than  $2^{n^2}$ :

**lemma**  $rhs\text{-less}: rhs < 2^{\wedge n^2}$

*<proof>*

It is clear that  $2^{n^2} \leq 8^T$  and that  $8^T < T!$  if  $T$  is sufficiently big. In this case, 'sufficiently big' means  $T \geq 20$  and thereby  $n \geq 7$ . We can therefore conclude that  $n$  must be less than 7.

**lemma**  $n\text{-less-}7: n < 7$

*<proof>*

We now only have 6 values for  $n$  to check. Together with the bounds that we obtained on  $k$ , this only leaves a few combinations of  $n$  and  $k$  to check,

and we do precisely that and find that  $n = k = 1$  and  $n = 2, k = 3$  are the only possible combinations.

**lemma** *n-k-in-set*:  $(n, k) \in \{(1, 1), (2, 3)\}$   
 ⟨proof⟩

**end**

Using this, deriving the final result is now trivial:

**theorem**  $\{(n, k). n > 0 \wedge k > 0 \wedge \text{fact } k = (\prod_{i < n}. 2^{\wedge n - 2^{\wedge i}} :: \text{nat})\} =$   
 $\{(1, 1), (2, 3)\}$   
 (is ?lhs = ?rhs)  
 ⟨proof⟩

**end**

### 3 Q5

**theory** *IMO2019-Q5*  
**imports** *Complex-Main*  
**begin**

Given a sequence  $(c_1, \dots, c_n)$  of coins, each of which can be heads ( $H$ ) or tails ( $T$ ), Harry performs the following process: Let  $k$  be the number of coins that show  $H$ . If  $k > 0$ , flip the  $k$ -th coin and repeat the process. Otherwise, stop.

What is the average number of steps that this process takes, averaged over all  $2^n$  coin sequences of length  $n$ ?

#### 3.1 Definition

We represent coins as Booleans, where *True* indicates  $H$  and *False* indicates  $T$ . Coin sequences are then simply lists of Booleans.

The following function flips the  $i$ -th coin in the sequence (in Isabelle, the convention is that the first list element is indexed with 0).

**definition** *flip* ::  $\text{bool list} \Rightarrow \text{nat} \Rightarrow \text{bool list}$  **where**  
*flip*  $xs\ i = xs[i := \neg xs\ i]$

**lemma** *flip-Cons-pos* [*simp*]:  $n > 0 \implies \text{flip } (x \# xs)\ n = x \# \text{flip } xs\ (n - 1)$   
 ⟨proof⟩

**lemma** *flip-Cons-0* [*simp*]:  $\text{flip } (x \# xs)\ 0 = (\neg x) \# xs$   
 ⟨proof⟩

**lemma** *flip-append1* [*simp*]:  $n < \text{length } xs \implies \text{flip } (xs @ ys)\ n = \text{flip } xs\ n @ ys$   
**and** *flip-append2* [*simp*]:  $n \geq \text{length } xs \implies n < \text{length } xs + \text{length } ys \implies$   
 $\text{flip } (xs @ ys)\ n = xs @ \text{flip } ys\ (n - \text{length } xs)$

*<proof>*

**lemma** *length-flip* [simp]:  $\text{length } (\text{flip } xs \ i) = \text{length } xs$   
*<proof>*

The following function computes the number of  $H$  in a coin sequence.

**definition** *heads* ::  $\text{bool list} \Rightarrow \text{nat}$  **where**  $\text{heads } xs = \text{length } (\text{filter } id \ xs)$

**lemma** *heads-True* [simp]:  $\text{heads } (\text{True} \ \# \ xs) = 1 + \text{heads } xs$   
**and** *heads-False* [simp]:  $\text{heads } (\text{False} \ \# \ xs) = \text{heads } xs$   
**and** *heads-append* [simp]:  $\text{heads } (xs \ @ \ ys) = \text{heads } xs + \text{heads } ys$   
**and** *heads-Nil* [simp]:  $\text{heads } [] = 0$   
*<proof>*

**lemma** *heads-Cons*:  $\text{heads } (x \ \# \ xs) = (\text{if } x \ \text{then } \text{heads } xs + 1 \ \text{else } \text{heads } xs)$   
*<proof>*

**lemma** *heads-pos*:  $\text{True} \in \text{set } xs \Longrightarrow \text{heads } xs > 0$   
*<proof>*

**lemma** *heads-eq-0* [simp]:  $\text{True} \notin \text{set } xs \Longrightarrow \text{heads } xs = 0$   
*<proof>*

**lemma** *heads-eq-0-iff* [simp]:  $\text{heads } xs = 0 \longleftrightarrow \text{True} \notin \text{set } xs$   
*<proof>*

**lemma** *heads-pos-iff* [simp]:  $\text{heads } xs > 0 \longleftrightarrow \text{True} \in \text{set } xs$   
*<proof>*

**lemma** *heads-le-length*:  $\text{heads } xs \leq \text{length } xs$   
*<proof>*

The following function performs a single step of Harry's process.

**definition** *harry-step* ::  $\text{bool list} \Rightarrow \text{bool list}$  **where**  
 $\text{harry-step } xs = \text{flip } xs \ (\text{heads } xs - 1)$

**lemma** *length-harry-step* [simp]:  $\text{length } (\text{harry-step } xs) = \text{length } xs$   
*<proof>*

The following is the measure function for Harry's process, i.e. how many steps the process takes to terminate starting from the given sequence. We define it like this now and prove the correctness later.

**function** *harry-meas* **where**  
 $\text{harry-meas } xs =$   
  ( $\text{if } xs = [] \ \text{then } 0$   
   $\text{else if } \text{hd } xs \ \text{then } 1 + \text{harry-meas } (\text{tl } xs)$   
   $\text{else if } \neg \text{last } xs \ \text{then } \text{harry-meas } (\text{butlast } xs)$   
   $\text{else let } n = \text{length } xs \ \text{in } \text{harry-meas } (\text{take } (n - 2) \ (\text{tl } xs)) + 2 * n - 1$ )

$\langle proof \rangle$   
**termination**  $\langle proof \rangle$

**lemmas**  $[simp\ del] = \text{harry-meas.simps}$

We now prove some simple properties of *harry-meas* and *harry-step*.

We prove a more convenient case distinction rule for lists that allows us to distinguish between lists starting with *True*, ending with *False*, and starting with *False* and ending with *True*.

**lemma** *head-last-cases*  $[case\ names\ Nil\ True\ False\ False-True]$ :  
**assumes**  $xs = [] \implies P$   
**assumes**  $\bigwedge ys. xs = True \# ys \implies P \ \bigwedge ys. xs = ys @ [False] \implies P$   
 $\bigwedge ys. xs = False \# ys @ [True] \implies P$   
**shows**  $P$   
 $\langle proof \rangle$

**lemma** *harry-meas-Nil*  $[simp]$ :  $\text{harry-meas } [] = 0$   
 $\langle proof \rangle$

**lemma** *harry-meas-True-start*  $[simp]$ :  $\text{harry-meas } (True \# xs) = 1 + \text{harry-meas } xs$   
 $\langle proof \rangle$

**lemma** *harry-meas-False-end*  $[simp]$ :  $\text{harry-meas } (xs @ [False]) = \text{harry-meas } xs$   
 $\langle proof \rangle$

**lemma** *harry-meas-False-True*:  $\text{harry-meas } (False \# xs @ [True]) = \text{harry-meas } xs + 2 * \text{length } xs + 3$   
 $\langle proof \rangle$

**lemma** *harry-meas-eq-0*  $[simp]$ :  
**assumes**  $True \notin \text{set } xs$   
**shows**  $\text{harry-meas } xs = 0$   
 $\langle proof \rangle$

If the sequence starts with *H*, the process runs on the remaining sequence until it terminates and then flips this *H* in another single step.

**lemma** *harry-step-True-start*  $[simp]$ :  
 $\text{harry-step } (True \# xs) = (\text{if } True \in \text{set } xs \text{ then } True \# \text{harry-step } xs \text{ else } False \# xs)$   
 $\langle proof \rangle$

If the sequence ends in *T*, the process simply runs on the remaining sequence as if it were not present.

**lemma** *harry-step-False-end*  $[simp]$ :  
**assumes**  $True \in \text{set } xs$   
**shows**  $\text{harry-step } (xs @ [False]) = \text{harry-step } xs @ [False]$

*<proof>*

If the sequence starts with  $T$  and ends with  $H$ , the process runs on the remaining sequence inbetween as if these two were not present, eventually leaving a sequence that consists entirely of  $T$  except for a single final  $H$ .

**lemma** *harry-step-False-True*:

**assumes**  $True \in set\ xs$

**shows**  $harry-step\ (False\ \#\ xs\ @\ [True]) = False\ \#\ harry-step\ xs\ @\ [True]$

*<proof>*

That sequence consisting only of  $T$  except for a single final  $H$  is then turned into an all- $T$  sequence in  $2n+1$  steps.

**lemma** *harry-meas-Falses-True [simp]*:  $harry-meas\ (replicate\ n\ False\ @\ [True]) = 2 * n + 1$

*<proof>*

**lemma** *harry-step-Falses-True [simp]*:

$n > 0 \implies harry-step\ (replicate\ n\ False\ @\ [True]) = True\ \#\ replicate\ (n - 1)\ False\ @\ [True]$

*<proof>*

### 3.2 Correctness of the measure

We will now show that *harry-meas* indeed counts the length of the process. As a first step, we will show that if there is a  $H$  in a sequence, applying a single step decreases the measure by one.

**lemma** *harry-meas-step-aux*:

**assumes**  $True \in set\ xs$

**shows**  $harry-meas\ xs = Suc\ (harry-meas\ (harry-step\ xs))$

*<proof>*

**lemma** *harry-meas-step*:  $True \in set\ xs \implies harry-meas\ (harry-step\ xs) = harry-meas\ xs - 1$

*<proof>*

Next, we show that the measure is zero if and only if there is no  $H$  left in the sequence.

**lemma** *harry-meas-eq-0-iff [simp]*:  $harry-meas\ xs = 0 \iff True \notin set\ xs$

*<proof>*

It follows by induction that if the measure of a sequence is  $n$ , then iterating the step less than  $n$  times yields a sequence with at least one  $H$  in it, but iterating it exactly  $n$  times yields a sequence that contains no more  $H$ .

**lemma** *True-in-funpow-harry-step*:

**assumes**  $n < harry-meas\ xs$

**shows**  $True \in set\ ((harry-step\ \sim\ n)\ xs)$

*<proof>*

**lemma** *True-notin-funpow-harry-step*:  $\text{True} \notin \text{set } ((\text{harry-step} \rightsquigarrow \text{harry-meas } xs))$   
 $xs)$   
 $\langle \text{proof} \rangle$

This shows that the measure is indeed the correct one: It is the smallest number such that iterating Harry's step that often yields a sequence with no heads in it.

**theorem** *harry-meas*  $xs = (\text{LEAST } n. \text{True} \notin \text{set } ((\text{harry-step} \rightsquigarrow n) xs))$   
 $\langle \text{proof} \rangle$

### 3.3 Average-case analysis

The set of all coin sequences of a given length.

**definition** *seqs where*  $seqs\ n = \{xs :: \text{bool list} \mid \text{length } xs = n\}$

**lemma** *length-seqs [dest]*:  $xs \in seqs\ n \implies \text{length } xs = n$   
 $\langle \text{proof} \rangle$

**lemma** *seqs-0 [simp]*:  $seqs\ 0 = \{\}\}$   
 $\langle \text{proof} \rangle$

The coin sequences of length  $n + 1$  are simply what is obtained by appending either  $H$  or  $T$  to each coin sequence of length  $n$ .

**lemma** *seqs-Suc*:  $seqs\ (\text{Suc } n) = (\lambda xs. \text{True} \# xs) \text{ ' } seqs\ n \cup (\lambda xs. \text{False} \# xs) \text{ ' } seqs\ n$   
 $\langle \text{proof} \rangle$

The set of coin sequences of length  $n$  is invariant under reversal.

**lemma** *seqs-rev [simp]*:  $rev \text{ ' } seqs\ n = seqs\ n$   
 $\langle \text{proof} \rangle$

Hence we get a similar decomposition theorem that appends at the end.

**lemma** *seqs-Suc'*:  $seqs\ (\text{Suc } n) = (\lambda xs. xs \text{ @ } [\text{True}]) \text{ ' } seqs\ n \cup (\lambda xs. xs \text{ @ } [\text{False}]) \text{ ' } seqs\ n$   
 $\langle \text{proof} \rangle$

**lemma** *finite-seqs [intro]*:  $\text{finite } (seqs\ n)$   
 $\langle \text{proof} \rangle$

**lemma** *card-seqs [simp]*:  $\text{card } (seqs\ n) = 2 \wedge n$   
 $\langle \text{proof} \rangle$

**lemmas** *seqs-code [code]*  $= seqs-0\ seqs-Suc$

The sum of the measures over all possible coin sequences of a given length (defined as a recurrence relation; correctness proven later).

**fun** *harry-sum* :: *nat*  $\Rightarrow$  *nat* **where**

*harry-sum* 0 = 0  
| *harry-sum* (Suc 0) = 1  
| *harry-sum* (Suc (Suc n)) = 2 \* *harry-sum* (Suc n) + (2 \* n + 4) \* 2 ^ n

**lemma** *Suc-Suc-induct*:  $P\ 0 \Longrightarrow P\ (\text{Suc}\ 0) \Longrightarrow (\bigwedge n. P\ n \Longrightarrow P\ (\text{Suc}\ n) \Longrightarrow P\ (\text{Suc}\ (\text{Suc}\ n))) \Longrightarrow P\ n$   
  <proof>

The recurrence relation really does describe the sum over all measures:

**lemma** *harry-sum-correct*:  $\text{harry-sum}\ n = \text{sum}\ \text{harry-meas}\ (\text{seqs}\ n)$   
  <proof>

**lemma** *harry-sum-closed-form-aux*:  $4 * \text{harry-sum}\ n = n * (n + 1) * 2 ^ n$   
  <proof>

Solving the recurrence gives us the following solution:

**theorem** *harry-sum-closed-form*:  $\text{harry-sum}\ n = n * (n + 1) * 2 ^ n \text{ div } 4$   
  <proof>

The average is now a simple consequence:

**definition** *harry-avg* **where**  $\text{harry-avg}\ n = \text{harry-sum}\ n / \text{card}\ (\text{seqs}\ n)$

**corollary**  $\text{harry-avg}\ n = n * (n + 1) / 4$   
  <proof>

**end**
