Abstract

We represent a theory *of* (a fragment of) Isabelle/HOL *in* Isabelle/HOL. The purpose of this exercise is to write packages for domain-specific specifications such as class models, B-machines, . . . , and generally speaking, any domain-specific languages whose abstract syntax can be defined by a HOL “datatype”. On this basis, the Isabelle code-generator can then be used to generate code for global context transformations as well as tactic code.

Consequently the package is geared towards parsing, printing and code-generation to the Isabelle API. It is at the moment not sufficiently rich for doing meta theory on Isabelle itself. Extensions in this direction are possible though.

Moreover, the chosen fragment is fairly rudimentary. However it should be easily adapted to one’s needs if a package is written on top of it. The supported API contains types, terms, transformation of global context like definitions and data-type declarations as well as infrastructure for Isar-setups.

This theory is drawn from the Featherweight OCL[1] project where it is used to construct a package for object-oriented data-type theories generated from UML class diagrams. The Featherweight OCL, for example, allows for both the direct execution of compiled tactic code by the Isabelle API as well as the generation of `.thy`-files for debugging purposes.

Gained experience from this project shows that the compiled code is sufficiently efficient for practical purposes while being based on a formal *model* on which properties of the package can be proven such as termination of certain transformations, correctness, etc.

Part I.

A Meta-Model for the Isabelle API

1. Initialization

```
theory Init
  imports isabelle-home/src/HOL/Isabelle-Main0
begin
```

1.1. Optimization on the String Datatype

The following types will allow to delay all concatenations on *integer list*, until we reach the end. As optimization, we also consider the use of *String.literal* besides *integer list*.

```
type-notation natural ( $\langle nat \rangle$ )
```

```
definition Succ  $x = x + 1$ 
```

```
datatype stringbase = ST String.literal
                  | ST' integer list
```

```
datatype abr-string =
  SS-base stringbase
  | String-concatWith abr-string abr-string list
```

```
syntax -string1 :: -  $\Rightarrow$  abr-string ( $\langle \langle (-) \rangle \rangle$ )
```

```
translations  $\langle x \rangle \Rightarrow$  CONST SS-base (CONST ST  $x$ )
```

```
syntax -string3 :: -  $\Rightarrow$  abr-string ( $\langle \langle \langle (-) \rangle \rangle \rangle$ )
```

```
translations  $\langle \langle x \rangle \rangle \Rightarrow$  CONST SS-base (CONST ST'  $x$ )
```

```
syntax -integer1 :: -  $\Rightarrow$  abr-string ( $\langle ^\circ (-) ^\circ \rangle$ )
```

```
translations  $^\circ x ^\circ \Rightarrow$  CONST SS-base (CONST ST' ((CONST Cons)  $x$  (CONST Nil)))
```

```
type-notation abr-string ( $\langle string \rangle$ )
```

1.2. Basic Extension of the Standard Library

1.2.1. Polymorphic Cartouches

We generalize the construction of cartouches for them to be used “polymorphically”, however the type inference is not automatic: types of all cartouche expressions will need to be specified earlier before their use (we will however provide a default type).

ML_⋄

```
structure Cartouche-Grammar = struct
  fun list-comb-mk cst n c = list-comb (Syntax.const cst, String-Syntax.mk-bits-syntax n c)
  val nil1 = Syntax.const @{const-syntax String.empty-literal}
  fun cons1 c l = list-comb-mk @{const-syntax String.Literal} 7 c $ l

  val default =
    [ ( char list
      , ( Const (@{const-syntax Nil}, @{typ char list})
        , fn c => fn l => Syntax.const @{const-syntax Cons} $ list-comb-mk @{const-syntax
Char} 8 c $ l
        , snd))
      , ( String.literal, (nil1, cons1, snd))
      , ( abr-string
        , ( nil1
          , cons1
          , fn (-, x) => Syntax.const @{const-syntax SS-base}
              $ (Syntax.const @{const-syntax ST}
                $ x))))]

end
>
```

ML_⋄

```
fun parse-translation-cartouche binding l f-integer accu =
  let val cartouche-type = Attrib.setup-config-string binding (K (fst (hd l)))
    (* if there is no type specified, by default we set the first element
    to be the default type of cartouches *) in
  fn ctxt =>
    let val cart-type = Config.get ctxt cartouche-type in
    case List.find (fn (s, -) => s = cart-type) l of
      NONE => error (Unregistered return type for the cartouche: \ ^ cart-type ^ \)
    | SOME (-, (nil0, cons, f)) =>
      string-tr f (f-integer, cons, nil0) accu (Symbol-Pos.cartouche-content o Symbol-Pos.explode)
    end
  end
end
>
```

parse-translation ⋄

```
[( @{syntax-const -cartouche-string}
  , parse-translation-cartouche @{binding cartouche-type} Cartouche-Grammar.default (K I)
  ())]
>
```

This is the special command which sets the type of subsequent cartouches. Note: here the given type is currently parsed as a string, one should extend it to be a truly “typed” type...

declare[[cartouche-type = abr-string]]

1.2.2. Operations on List

  TFree string sort |
  TVar indexname sort
datatype term =
  Const string typ |
  Free string typ |
  Var indexname typ |
  Bound nat |
  Abs string typ term |
  App term term (infixl <$> 200)
```

2.1.2. Operations of Fold, Map, ..., on the Meta-Model

```
fun map-Const where
  map-Const f expr = ( $\lambda$  Const s ty  $\Rightarrow$  Const (f s ty) ty
    | Free s ty  $\Rightarrow$  Free s ty
    | Var i ty  $\Rightarrow$  Var i ty
    | Bound n  $\Rightarrow$  Bound n
    | Abs s ty term  $\Rightarrow$  Abs s ty (map-Const f term)
    | App term1 term2  $\Rightarrow$  App (map-Const f term1)
                              (map-Const f term2))
  expr

fun fold-Const where
  fold-Const f accu expr = ( $\lambda$  Const s -  $\Rightarrow$  f accu s
    | Abs - - term  $\Rightarrow$  fold-Const f accu term
    | App term1 term2  $\Rightarrow$  fold-Const f (fold-Const f accu term1) term2
    | -  $\Rightarrow$  accu)
```

expr

```
fun fold-Free where
  fold-Free f accu expr = (λ Free s - ⇒ f accu s
    | Abs - - term ⇒ fold-Free f accu term
    | App term1 term2 ⇒ fold-Free f (fold-Free f accu term1) term2
    | - ⇒ accu)
    expr

end
```

2.2. SML Meta-Model aka. AST definition of SML

```
theory Meta-SML
imports ../Init
begin
```

2.2.1. Type Definition

The following datatypes beginning with **semi__** represent semi-concrete syntax, deliberately not minimal abstract syntax like (Pure) Term, this is for example to facilitate the pretty-printing process, or for manipulating recursively data-structures through an abstract and typed API.

```
datatype semi-val-fun = Sval
    | Sfun
```

```
datatype semi-term' = SML-string string
    | SML-rewrite semi-val-fun semi-term' — left string — symb rewriting
semi-term' — right
    | SML-basic string list
    | SML-binop semi-term' string semi-term'
    | SML-annot semi-term' string — type

2.3. Isabelle Meta-Model aka. AST definition of Isabelle

```

theory Meta-Isabelle
imports Meta-Pure

```

begin

2.3.1. Type Definition

The following datatypes beginning with **semi__** represent semi-concrete syntax, deliberately not minimal abstract syntax like (Pure) Term, this is for example to facilitate the pretty-printing process, or for manipulating recursively data-structures through an abstract and typed API.

```
datatype semi--typ = Typ-apply semi--typ semi--typ list
  | Typ-apply-bin string — binop semi--typ semi--typ
  | Typ-apply-paren string — left string — right semi--typ
  | Typ-base string
```

```
datatype datatype = Datatype string — name
  (string — name × semi--typ list — arguments) list — constructors
```

```
datatype type-synonym = Type-synonym string — name
  string list — parametric variables
  semi--typ — content
```

```
datatype semi--term = Term-rewrite semi--term — left string — symb rewriting semi--term
— right
  | Term-basic string list
  | Term-annot semi--term semi--typ
  | Term-bind string — symbol semi--term — arg semi--term
  | Term-fun-case semi--term — value option — none: function (semi--term —
pattern × semi--term — to return) list
  | Term-apply semi--term semi--term list
  | Term-paren string — left string — right semi--term
  | Term-if-then-else semi--term semi--term semi--term
  | Term-term string list — simulate a pre-initialized context (de bruijn variables
under "lam")
  term — usual continuation of inner syntax term
```

```
datatype type-notation = Type-notation string — name
  string — content
```

```
datatype instantiation = Instantiation string — name
  string — name in definition
  semi--term
```

```
datatype overloading = Overloading string — name consts semi--term

3.1.2. Generic Locale for Parsing

```
locale Parse =  
  fixes ext :: string  $\Rightarrow$  string  
  
  — (effective) first order  
  fixes of-string :: ('a  $\Rightarrow$  'a list  $\Rightarrow$  'a)  $\Rightarrow$  (string  $\Rightarrow$  'a)  $\Rightarrow$  string  $\Rightarrow$  'a  
  fixes of-stringbase :: ('a  $\Rightarrow$  'a list  $\Rightarrow$  'a)  $\Rightarrow$  (string  $\Rightarrow$  'a)  $\Rightarrow$  stringbase  $\Rightarrow$  'a  
  fixes of-nat :: ('a  $\Rightarrow$  'a list  $\Rightarrow$  'a)  $\Rightarrow$  (string  $\Rightarrow$  'a)  $\Rightarrow$  natural  $\Rightarrow$  'a  
  fixes of-unit :: (string  $\Rightarrow$  'a)  $\Rightarrow$  unit  $\Rightarrow$  'a  
  fixes of-bool :: (string  $\Rightarrow$  'a)  $\Rightarrow$  bool  $\Rightarrow$  'a  
  
  — (simulation) higher order  
  fixes Of-Pair Of-Nil Of-Cons Of-None Of-Some :: string  
begin  
  
definition of-pair a b f1 f2 = ( $\lambda f. \lambda(c, d) \Rightarrow f\ c\ d$ )  
  (ap2 a (b Of-Pair) f1 f2)  
  
definition of-list a b f = ( $\lambda f0. \text{rec-list } f0\ o\ co1\ K$ )  
  (b Of-Nil)  
  (ar2 a (b Of-Cons) f)  
  
definition of-option a b f = rec-option  
  (b Of-None)  
  (ap1 a (b Of-Some) f)  
  
end  
  
lemmas [code] =  
  Parse.of-pair-def  
  Parse.of-list-def  
  Parse.of-option-def
```

This theory and all the deriving one could also be prefixed by “print” instead of “parse”. In any case, we are converting (or printing) the above datatypes to another format, and finally this format will be “parsed” by Isabelle!

end

3.2. Instantiating the Parser of (Pure) Term

```
theory Parser-Pure  
imports Meta-Pure  
  Parser-init  
begin
```

3.2.1. Main

```
context Parse
```

begin

4.1.6. Generic Locale for Printing

```
locale Print =  
  fixes To-string :: string  $\Rightarrow$  ml-string  
  fixes To-nat :: nat  $\Rightarrow$  ml-int  
begin  
  declare[[cartouche-type' = fun_printf]]  
end
```

As remark, printing functions (like *sprintf5*...) are currently weakly typed in Isabelle, we will continue the typing using the type system of target languages.

end

5. Main

We present two solutions for obtaining an Isabelle file.

5.1. Static Meta Embedding with Exportation

```
theory Generator-static
imports Printer ../../Antiquote-Setup
begin
```

In the “static” solution: the user manually generates the Isabelle file after writing by hand a Toy input to translate. The input is not written with the syntax of the Toy Language, but with raw Isabelle constructors.

5.1.1. Giving an Input to Translate

```
definition Design =
  (let n = λn1 n2. ToyTyObj (ToyTyCore-pre n1) (case n2 of None ⇒ [] | Some n2 ⇒ [[ToyTyCore-pre
n2]]))
  ; mk = λn l. toy-class-raw.make n l [] False in
  [ mk (n ⟨Galaxy⟩ None) [(⟨sound⟩, ToyTy-raw ⟨unit⟩), (⟨moving⟩, ToyTy-raw ⟨bool⟩)]
  , mk (n ⟨Planet⟩ (Some ⟨Galaxy⟩)) [(⟨weight⟩, ToyTy-raw ⟨nat⟩)]
  , mk (n ⟨Person⟩ (Some ⟨Planet⟩)) [(⟨salary⟩, ToyTy-raw ⟨int⟩)] ]
```

Since we are in a Isabelle session, at this time, it becomes possible to inspect with the command **value** the result of the translations applied with *Design*. A suitable environment should nevertheless be provided, one can typically experiment this by copying-pasting the following environment initialized in the above *main*:

```
definition main =
  (let n = λn1. ToyTyObj (ToyTyCore-pre n1) []
  ; ToyMult = λm r. toy-multiplicity.make [m] r [Set] in
  write-file
  (compiler-env-config.extend
    (compiler-env-config-empty True None (oidInit (Oid 0)) Gen-only-design (None, False)
    [ D-output-disable-thy := False
    , D-output-header-thy := Some (⟨Design-generated⟩
      , [⟨../Toy-Library⟩
      , [⟨../embedding/Generator-dynamic-sequential⟩] ]))
  ( L.map (META-class-raw Floor1) Design
    @@@@ [ META-association (toy-association.make
      ToyAssTy-association
```

```

      (ToyAssRel [ (n ⟨Person⟩, ToyMult (Mult-star, None) None)
                  , (n ⟨Person⟩, ToyMult (Mult-nat 0, Some (Mult-nat 1))
                    (Some ⟨boss⟩))]))
    , META-flush-all ToyFlushAll]
    , None)))

```

5.1.2. Statically Executing the Exportation

```

apply_code_printing ()
export_code main
(* in Haskell *)
(* in OCaml module_name M *)
(* in Scala module_name M *)
(* in SML    module_name M *)

```

After the exportation and executing the exported, we obtain an Isabelle `.thy` file containing the generated code associated to the above input.

end

5.2. Dynamic Meta Embedding with Reflection

```

theory Generator-dynamic-sequential
imports Printer
  ../isabelle-home/src/HOL/Isabelle-Main2begin

```

In the “dynamic” solution: the exportation is automatically handled inside Isabelle/jEdit. Inputs are provided using the syntax of the Toy Language, and in output we basically have two options:

- The first is to generate an Isabelle file for inspection or debugging. The generated file can interactively be loaded in Isabelle/jEdit, or saved to the hard disk. This mode is called the “deep exportation” mode or shortly the “deep” mode. The aim is to maximally automate the process one is manually performing in `Generator_static.thy`.
- On the other hand, it is also possible to directly execute in Isabelle/jEdit the generated file from the random access memory. This mode corresponds to the “shallow reflection” mode or shortly “shallow” mode.

In both modes, the reflection is necessary since the main part used by both was defined at Isabelle side. As a consequence, experimentations in “deep” and “shallow” are performed without leaving the editing session, in the same as the one the meta-compiler is actually running.

```

apply-code-printing-reflect ⟨
  val stdout-file = Unsynchronized.ref
⟩

```

This variable is not used in this theory (only in `Generator_static.thy`), but needed for well typechecking the reflected SML code.

```

code-reflect' open META
functions
  fold-thy-deep fold-thy-shallow

  write-file

  compiler-env-config-reset-all
  compiler-env-config-update
  oidInit
  D-output-header-thy-update
  map2-ctxt-term
  check-export-code

  isabelle-apply isabelle-of-compiler-env-config

```

5.2.1. Interface Between the Reflected and the Native

```

A Toy Example

5.3. A Toy Library for Objects in a State

```

theory Toy-Library
imports Main
begin

type-notation option ( $\langle \langle - \rangle \perp \rangle$ )
notation Some ( $\langle \lfloor (-) \rfloor \rangle$ )

fun drop :: 'α option  $\Rightarrow$  'α ( $\langle \lfloor (-) \rfloor \rangle$ )
where drop-lift[simp]:  $\lceil \lfloor v \rfloor \rceil = v$ 

type-synonym oid = nat

type-synonym 'α val' = unit  $\Rightarrow$  'α
type-notation val' ( $\langle \cdot (-) \rangle$ )

record ('α)state =
  heap :: oid  $\rightarrow$  'α
  assocs :: oid  $\rightarrow$  ((oid list) list) list

lemmas [simp, code-unfold] = state.defs

end

```

5.4. Example: A Class Model Converted into a Theory File

5.4.1. Introduction

```

theory
  Design-deep
imports
  ../embedding/Generator-dynamic-sequential
  ../../Antiquote-Setup
begin

```

In this example, we configure our package to generate a `.thy` file, without executing the associated generated code contained in this `.thy` file (c.f. `Design_shallow.thy` for a direct evaluation). This mode is particularly relevant for debugging purposes: while by default no evaluation occurs, the generated files (and their proofs!) can be executed on a step by step basis, depending on how we interact with the output window (by selectively clicking on what is generated).

After clicking on the generated content, the newly inserted content could depend on some theories which are not loaded by this current one. In this case, it is necessary to manually add all the needed dependencies above after the keyword **imports**. One should compare this current theory with `Design_shallow.thy` to see the differences of imported theories, and which ones to manually import (whenever an error happens).

```
generation-syntax [ ]
```

```
generation_syntax
[ deep
  (generation_semantics [ design ])
  (THEORY Design_generated)
  (IMPORTS ["../Toy_Library", "../Toy_Library_Static"]
    "../embedding/Generator_dynamic_sequential")
  SECTION
  (*SORRY*) (*no_dirty*)
  [ (* in Haskell *)
    (* in OCaml module_name M *)
    (* in Scala module_name M *)
    in SML module_name M ]
  (output_directory "../document_generated")
  (*, syntax_print*) ]
```

While in theory it is possible to set the **deep** mode for generating in all target languages, i.e. by writing [*in Haskell, in OCaml module-name M, in Scala module-name M, in SML module-name M*], usually using only one target is enough, since the task of all target is to generate the same Isabelle content. However in case one language takes too much time to setup, we recommend to try the generation with another target language, because all optimizations are currently not (yet) seemingly implemented for all target languages, or differently activated.

5.4.2. Designing Class Models (I): Basics

The following example shows the definitions of a set of classes, called the “universe” of classes. Instead of providing a single command for building all the complete universe of classes directly in one block, we are constructing classes one by one. So globally the universe describing all classes is partial, it will only be fully constructed when all classes will be finished to be defined.

This allows to define classes without having to follow a particular order of definitions. Here *Atom* is defined before the one of *Molecule* (*Molecule* will come after):

```
Class Atom < Molecule
  Attributes size : Integer
End
```

The “blue” color of **End** indicates that **End** is not a “green” keyword. **End** and **Class** are in fact similar, they belong to the group of meta-commands (all meta-commands are defined in *Isabelle-Meta-Model.Generator-dynamic-sequential*). At run-time and in **deep** mode, the semantics of all meta-commands are approximately similar: all meta-commands displays some quantity of Isabelle code in the output window (as long as

meta-commands are syntactically correctly formed). However each meta-command is unique because what is displayed in the output window depends on the sequence of all meta-commands already encountered before (and also depends on arguments given to the meta-commands).

One particularity of **End** is to behave as the identity function when **End** is called without arguments. As example, here we are calling lots of **End** without arguments, and no Isabelle code is generated.

End End End

We remark that, like any meta-commands, **End** could have been written anywhere in this theory, for example before **Class** or even before **generation-syntax**... Something does not have to be specially opened before using an **End**.

Class *Molecule* < *Person*

As example, here no **End** is written.

The semantics of **End** is further precised here. We earlier mentioned that the universe of classes is partially constructed, but one can still examine what is partially constructed, and one possibility is to use **End** for doing so.

End can be seen as a lazy meta-command:

- without parameters, no code is generated,
- with some parameters (e.g., the symbol !), it forces the generation of the computation of the universe, by considering all already encountered classes. Then a partial representation of the universe can be interactively inspected.

Class *Galaxy*

Attributes *wormhole* : *UnlimitedNatural*
is-sound : *Void*

End!

At this position, in the output window, we can observe for the first time some generated Isabelle code, corresponding to the partial universe of classes being constructed.

Note: By default, *Atom* and *Molecule* are not (yet) present in the shown universe because *Person* has not been defined in a separate line (unlike *Galaxy* above).

Class *Person* < *Galaxy*

Attributes *salary* : *Integer*
boss : *Person*
is-meta-thinking : *Boolean*

There is not only **End** which forces the computation of the universe, for example **Instance** declares a set of objects belonging to the classes earlier defined, but the entire universe is needed as knowledge, so there is no choice than forcing the generation of the universe.

Instance $X_{Person1} :: Person = [salary = 1300 , boss = X_{Person2}]$
and $X_{Person2} :: Person = [salary = 1800]$

Here we will call **Instance** again to show that the universe will not be computed again since it was already computed in the previous **Instance**.

Instance $X_{Person3} :: Person = [salary = 1]$

However at any time, the universe can (or will) automatically be recomputed, whenever we are adding meanwhile another class:

```
(* Class Big_Bang < Atom (* This will force the creation of a new universe.
*) *)
```

As remark, not only the universe is recomputed, but the recomputation takes also into account all meta-commands already encountered. So in the new setting, $X_{Person1}$, $X_{Person2}$ and $X_{Person3}$ will be resurrected... after the *Big-Bang*.

5.4.3. Designing Class Models (II): Jumping to Another Semantic Floor

Until now, meta-commands was used to generate lines of code, and these lines belong to the Isabelle language. One particularity of meta-commands is to generate pieces of code containing not only Isabelle code but also arbitrary meta-commands. In **deep** mode, this is particularly not a danger for meta-commands to generate themselves (whereas for **shallow** the recursion might not terminate).

In this case, such meta-commands must automatically generate the appropriate call to **generation-syntax** beforehand. However this is not enough, the compiling environment (comprising the history of meta-commands) are changing throughout the interactive evaluations, so the environment must also be taken into account and propagated when meta-commands are generating themselves. For example, the environment is needed for consultation whenever resurrecting objects, recomputing the universe or accessing the hierarchy of classes being defined.

As a consequence, in the next example a line **setup** is added after **generation-syntax** for bootstrapping the state of the compiling environment.

State $\sigma_1 =$
 $[([salary = 1000 , boss = self\ 1] :: Person)$
 $, ([salary = 1200] :: Person)$
 $, ([salary = 2600 , boss = self\ 3] :: Person)$
 $, X_{Person1}$
 $, ([salary = 2300 , boss = self\ 2] :: Person)$
 $, X_{Person2}]$

State $\sigma_1' =$
 $[X_{Person1}$
 $, X_{Person2}$
 $, X_{Person3}]$

In certain circumstances, the command **setup** must be added again between some par-

ticular interleaving of two meta-commands and this may not depend on the presence of **generation-syntax** (which is defined only once when generating the first meta-command). For more details, one can refer to the source code of *ignore-meta-header* and *bootstrap-floor*.

PrePost $\sigma_1 \sigma_1'$

The generation of meta-commands allows to perform various extensions on the Toy language being embedded, without altering the semantics of a particular command. **PrePost** usually only takes “bound variables” as parameters (not arbitrary λ -terms), however the semantics of **PrePost** was extended to mimic the support of some particular terms not restricted to variables. This extension was implemented by executing some steps of “ ζ -reductions rewriting rules” operating on the meta-level of commands. First, it is at least needed to extend the syntax of expressions accepted by **PrePost**, we then modify the parsing so that a larger subset of λ -terms can be given as parameters. Starting from this expression:

```
(* PrePost \<sigma>\<^sub>1 [ ([ salary = 1000 , boss = self 1 ] :: Person)
] *)
```

the rewriting begins with a first call to the next semantic floor, we obtain the following meta-commands (where **PrePost** [shallow] is an expression in normal form):

```
(* State WFF_10_post = [ ([ "salary" = 1000, "boss" = self 1 ] :: Person)
]
```

```
PrePost[shallow] \<sigma>\<^sub>1 WFF_10_post *) (WFF-10-post is an automatically generated name).
```

The rewriting of the above **State** is performed in its turn. Finally the overall ultimately terminates when reaching **Instance** being already in normal form:

```
(* Instance WFF_10_post_object0 :: Person = [ "salary" = 1000, "boss" = [
] ]
```

```
State[shallow] WFF_10_post = [ WFF_10_post_object0 ]
```

```
PrePost[shallow] \<sigma>\<^sub>1 WFF_10_post *)
```

5.4.4. Designing Class Models (III): Interaction with (Pure) Term

Meta-commands are obviously not restricted to manipulate expressions in the Outer Syntax level. It is possible to build meta-commands so that Inner Syntax expressions are directly parsed. However the dependencies of this theory have been minimized so that experimentations and debugging can easily occur in **deep** mode (this file only depends on *Isabelle-Meta-Model.Generator-dynamic-sequential*). Since the Inner Syntax expressions would perhaps manipulate expressions coming from other theories than *Isabelle-Meta-Model.Generator-dynamic-sequential*, it can be desirable to consider the Inner Syntax container as a string and leave the parsing for subsequent semantic floors. This is what is implemented here:

```
Context Person :: content ()
  Post "><"
```

Here the expression $><$ is not well-typed in Isabelle, but an error is not raised because the above expression is not (yet) parsed as an Inner Syntax element¹.

However, this is not the same for the resulting generated meta-command:

```
Context [shallow] Person :: content ()  
  Post : "(\<lambda> result self. (><))"
```

and an error is immediately raised because the parsing of Inner Syntax expressions is activated in this case.

For example, one can put the mouse, with the CTRL gesture, over the variable a , b or c to be convinced that they are free variables compared with above:

```
Context[shallow] Person :: content ()  
  Post :  $a + b = c$ 
```

5.4.5. Designing Class Models (IV): Saving the Generated to File

The experimentations usually finish by saving all the universe and generated Isabelle theory to the hard disk:

```
(* generation_syntax deep flush_all *)
```

5.4.6. Designing Class Models (V): Inspection of Generated Files

According to options given to the (first) command **generation-syntax** above, we retrieve the first generated file in the mentioned directory: `../document_generated/Design_generated.thy`.

Because this file still contains meta-commands, we are here executing again a new generating step inside this file, the new result becomes saved in `../document_generated/Design_generated_generated.thy`. As remark, in this last file, the dependency to *Isabelle-Meta-Model.Generator-dynamic-sequential* was automatically removed because the meta-compiler has detected the absence of meta-commands in the generated content.

Note: While the first generated file is intended to be always well-typed, it can happen that subsequent generations will lead to a not well-typed file. This is because the meta-compiler only saves the history of meta-commands. In case some “native” Isabelle declarations are generated among meta-commands, then these Isabelle declarations are not saved by the meta-compiler, so these declarations will not be again generated. Anyway, we see potential solutions for solving this and they would perhaps be implemented in a future version of the meta-compiler...

end

¹In any case an error will not be raised, because the above code is written in verbatim in the real `.thy` file, however one can copy-paste this code out of the verbatim scope to see that no errors are really raised. For presentation purposes, it was embedded in verbatim because we will later discuss about meta-commands generating Isabelle code, and then what is generated by this meta-command is of course not well-typed!

5.5. Example: A Class Model Interactively Executed

5.5.1. Introduction

```
theory
  Design-shallow
imports
  ../Toy-Library
  ../Toy-Library-Static
  ../embedding/Generator-dynamic-sequential
  ../Antiquote-Setup
begin
```

In this example, we configure our package to execute tactic SML code (corresponding to some generated `.thy` file, `Design_deep.thy` details how to obtain such generated `.thy` file). Since SML code are already compiled (or reflected) and bound with the native Isabelle API in *Isabelle-Meta-Model.Generator-dynamic-sequential*, nothing is generated in this theory. The system only parses arguments given to meta-commands and immediately calls the corresponding compiled functions.

The execution time is comparatively similar as if tactics were written by hand, except that the generated SML code potentially inherits all optimizations performed by the raw code generation of Isabelle (if any).

```
generation-syntax [ shallow (generation-semantic [ design ])
]

```

The configuration in **shallow** mode is straightforward: in this mode **generation-syntax** basically terminates in $O(1)$.

5.5.2. Designing Class Models (I): Basics

```
Class Atom < Molecule
  Attributes size : Integer
End
```

```
End End End
```

```
Class Molecule < Person
```

```
Class Galaxy
  Attributes wormhole : UnlimitedNatural
             is-sound : Void
End!
```

```
Class Person < Galaxy
  Attributes salary : Integer
             boss : Person
             is-meta-thinking : Boolean
```

```

Instance  $X_{Person1} :: Person = [ salary = 1300 , boss = X_{Person2} ]$ 
  and  $X_{Person2} :: Person = [ salary = 1800 ]$ 

```

```

Instance  $X_{Person3} :: Person = [ salary = 1 ]$ 

```

5.5.3. Designing Class Models (II): Jumping to Another Semantic Floor

5.5.4. Designing Class Models (III): Interaction with (Pure) Term

Here in **shallow** mode, the following expression is directly rejected:

```

Context Person :: content ()
  Post "><"

Context[shallow]  $Person :: content ()$ 
  Post :  $a + b = c$ 

end

```

Part III.

Appendix

A. Grammars of Commands

A.1. Main Setup of Meta Commands

generation-syntax : *theory* $\rightarrow$ *theory*

syntax

semantics

deep-embedding

export-code

long-or-dirty

generation-syntax sets the behavior of all incoming meta-commands. By default, without firstly writing **generation-syntax**, meta-commands will only print in output what they have parsed, this is similar as giving to **generation-syntax** a non-empty list having only **syntax-print** as elements (on the other hand, nothing is printed when an empty list is received). Additionally **syntax-print** can be followed by an integer indicating the printing depth in output, similar as declaring *ML-print-depth* with an integer, but the global option **syntax-print** is restricted to meta-commands. Besides the printing of syntaxes, several options are provided to further analyze the semantics of languages being embedded, and tell if their evaluation should occur immediately using the **shallow** mode, or to only display what would have been evaluated using the **deep** mode (i.e., to only show the generated Isabelle content in the output window).

Since several occurrences of **deep**, **shallow** or **syntax-print** can appear in the parameterizing list, for each meta-command the overall evaluation respects the order of events given in the list (from head to tail). At the time of writing, it is only possible to evaluate this list sequentially: the execution stops as soon as one first error is raised, thus ignoring remaining events.

generation-syntax deep flush-all performs as side effect the writing of all the generated Isabelle contents to the hard disk (all at the calling time), by iterating the saving for each **deep** mode in the list. In particular, this is only effective if there is at least one **deep** mode earlier declared.

As a side note, target languages for the **deep** mode currently supported are: Haskell, OCaml, Scala and SML. So in principle, all these targets generate the same Isabelle content and exit correctly. However, depending on the intended use, exporting with some targets may be more appropriate than other targets:

- For efficiency reasons, the meta-compiler has implemented a particular optimization for accelerating the process of evaluating incoming meta-commands. By default in Haskell and OCaml, the meta-compiler (at HOL side) is exported only

once, during the **generation-syntax** step. Then all incoming meta-commands are considered as arguments sent to the exported meta-compiler. As a compositionality aspect, these arguments are compiled then linked together with the (already compiled) meta-compiler, but this implies the use of one call of *unsafeCoerce* in Haskell and one *Obj.magic* statement in OCaml (otherwise another solution would be to extract the meta-compiler as a functor). Similar optimizations are not yet implemented for Scala and are only half-implemented for the SML target (which basically performs a step of marshallng to string in Isabelle/ML).

- For safety reasons, it simply suffices to extract all the meta-compiler together with the respective arguments in front of each incoming meta-commands everytime, then the overall needs to be newly compiled everytime. This is the current implemented behavior for Scala. For Haskell, OCaml and SML, it was also the default behavior in a prototyping version of the compiler, as a consequence one can restore that functionality for future versions.

Concerning the semantics of generated contents, if lemmas and proofs are generated, **SORRY** allows to explicitly skip the evaluation of all proofs, irrespective of the presence of **sorry** or not in generated proofs. In any cases, the semantics of **sorry** has not been overloaded, e.g., red background may appear as usual.

Finally **generation-semantic**s is a container for specifying various options for varying the semantics of languages being embedded. For example, **design** and **analysis** are two options for specifying how the modelling of objects will be represented in the Toy Language. Similarly, this would be a typical place for options like *eager* or *lazy* for choosing how the evaluation should happen...

A.2. All Meta Commands of the Toy Language

A.3. Extensions of Isabelle Commands

code-reflect' : *theory* $\rightarrow$ *theory*

code-reflect' has the same semantics as **code-reflect** except that it additionally contains the option **open** inspired from the command **export-code** (with the same semantics).

lazy-code-printing : *theory* $\rightarrow$ *theory*
apply-code-printing : *theory* $\rightarrow$ *theory*
apply-code-printing-reflect : *local-theory* $\rightarrow$ *local-theory*

lazy-code-printing has the same semantics as **code-printing** or **ML**, except that no side effects occur until we give more details about its intended future semantics: this will be precised by calling **apply-code-printing** or **apply-code-printing-reflect**.

apply-code-printing repeatedly calls **code-printing** to all previously registered elements with **lazy-code-printing** (the order is preserved).

apply-code-printing-reflect repeatedly calls **ML** to all previously registered elements with **lazy-code-printing** (the order is preserved). As a consequence, code for other targets (Haskell, OCaml, Scala) are ignored. Moreover before the execution of the overall, it is possible to give an additional piece of SML code as argument to priorly execute.

B. Content of the Directory `isabelle_home`

B.1. Extensions for Cartouches

- `./src/HOL/ex/Isabelle_Cartouche_Examples.thy` *Main0:*
Some functions have been generalized for supporting cartouches.

B.2. Other Changes

- `./src/Tools/Code/Isabelle_code_runtime.thy` *Main1:*
The option *open* was introduced in this file for the definition of *code_reflect'*.
- `./src/Tools/Code/Isabelle_code_target.thy` *Main1:*
Some signatures was removed for exposing the main structure, we have also defined at the end the implementation of *lazy_code_printing*, *apply_code_printing* and *apply_code_printing_reflect*.
- `./src/Pure/Isar/Isabelle_typedec1.thy` *Main2:*
Short modification of the argument lifting a *binding* to a *binding option* with some signatures removed.

C. Content of One Generated File (as example)

```
theory Design-generated-generated imports ../Toy-Library ../Toy-Library-Static begin
```

For certain concepts like classes and class-types, only a generic definition for its resulting semantics can be given. Generic means, there is a function outside HOL that “compiles” a concrete, closed-world class diagram into a “theory” of this data model, consisting of a bunch of definitions for classes, accessors, method, casts, and tests for actual types, as well as proofs for the fundamental properties of these operations in this concrete data model.

Our data universe consists in the concrete class diagram just of node’s, and implicitly of the class object. Each class implies the existence of a class type defined for the corresponding object representations as follows:

```
datatype ty $\mathcal{E}\mathcal{X}\mathcal{T}_{Atom}$  = mk $\mathcal{E}\mathcal{X}\mathcal{T}_{Atom}$  oid oid list option int option bool option nat option unit option
datatype ty $\mathcal{A}tom$  = mk $\mathcal{A}tom$  ty $\mathcal{E}\mathcal{X}\mathcal{T}_{Atom}$  int option
datatype ty $\mathcal{E}\mathcal{X}\mathcal{T}_{Molecule}$  = mk $\mathcal{E}\mathcal{X}\mathcal{T}_{Molecule-Atom}$  ty $\mathcal{A}tom$ 
| mk $\mathcal{E}\mathcal{X}\mathcal{T}_{Molecule}$  oid oid list option int option bool option nat option unit option
datatype ty $\mathcal{M}olecule$  = mk $\mathcal{M}olecule$  ty $\mathcal{E}\mathcal{X}\mathcal{T}_{Molecule}$ 
datatype ty $\mathcal{E}\mathcal{X}\mathcal{T}_{Person}$  = mk $\mathcal{E}\mathcal{X}\mathcal{T}_{Person-Molecule}$  ty $\mathcal{M}olecule$ 
| mk $\mathcal{E}\mathcal{X}\mathcal{T}_{Person-Atom}$  ty $\mathcal{A}tom$ 
| mk $\mathcal{E}\mathcal{X}\mathcal{T}_{Person}$  oid nat option unit option
datatype ty $\mathcal{P}erson$  = mk $\mathcal{P}erson$  ty $\mathcal{E}\mathcal{X}\mathcal{T}_{Person}$  oid list option int option bool option
datatype ty $\mathcal{E}\mathcal{X}\mathcal{T}_{Galaxy}$  = mk $\mathcal{E}\mathcal{X}\mathcal{T}_{Galaxy-Person}$  ty $\mathcal{P}erson$ 
| mk $\mathcal{E}\mathcal{X}\mathcal{T}_{Galaxy-Molecule}$  ty $\mathcal{M}olecule$ 
| mk $\mathcal{E}\mathcal{X}\mathcal{T}_{Galaxy-Atom}$  ty $\mathcal{A}tom$ 
| mk $\mathcal{E}\mathcal{X}\mathcal{T}_{Galaxy}$  oid
datatype ty $\mathcal{G}alaxy$  = mk $\mathcal{G}alaxy$  ty $\mathcal{E}\mathcal{X}\mathcal{T}_{Galaxy}$  nat option unit option
datatype ty $\mathcal{E}\mathcal{X}\mathcal{T}_{ToyAny}$  = mk $\mathcal{E}\mathcal{X}\mathcal{T}_{ToyAny-Galaxy}$  ty $\mathcal{G}alaxy$ 
| mk $\mathcal{E}\mathcal{X}\mathcal{T}_{ToyAny-Person}$  ty $\mathcal{P}erson$ 
| mk $\mathcal{E}\mathcal{X}\mathcal{T}_{ToyAny-Molecule}$  ty $\mathcal{M}olecule$ 
| mk $\mathcal{E}\mathcal{X}\mathcal{T}_{ToyAny-Atom}$  ty $\mathcal{A}tom$ 
| mk $\mathcal{E}\mathcal{X}\mathcal{T}_{ToyAny}$  oid
datatype ty $\mathcal{T}oyAny$  = mk $\mathcal{T}oyAny$  ty $\mathcal{E}\mathcal{X}\mathcal{T}_{ToyAny}$ 
```

Now, we construct a concrete “universe of ToyAny types” by injection into a sum type containing the class types. This type of ToyAny will be used as instance for all respective type-variables.

```

datatype  $\mathfrak{A}$  = inAtom tyAtom
                | inMolecule tyMolecule
                | inPerson tyPerson
                | inGalaxy tyGalaxy
                | inToyAny tyToyAny

```

Having fixed the object universe, we can introduce type synonyms that exactly correspond to Toy types. Again, we exploit that our representation of Toy is a “shallow embedding” with a one-to-one correspondance of Toy-types to types of the meta-language HOL.

```

type-synonym Atom =  $\langle\langle ty_{Atom} \rangle_{\perp} \rangle_{\perp}$ 
type-synonym Molecule =  $\langle\langle ty_{Molecule} \rangle_{\perp} \rangle_{\perp}$ 
type-synonym Person =  $\langle\langle ty_{Person} \rangle_{\perp} \rangle_{\perp}$ 
type-synonym Galaxy =  $\langle\langle ty_{Galaxy} \rangle_{\perp} \rangle_{\perp}$ 
type-synonym ToyAny =  $\langle\langle ty_{ToyAny} \rangle_{\perp} \rangle_{\perp}$ 

```
