Subresultants*

Sebastiaan Joosten, René Thiemann and Akihisa Yamada

April 18, 2024

Abstract

We formalize the theory of subresultants and the subresultant polynomial remainder sequence as described by Brown and Traub. As a result, we obtain efficient certified algorithms for computing the resultant and the greatest common divisor of polynomials.

Contents

1 Introduction

Computing the gcd of two polynomials can be done via the Euclidean algorithm, if the domain of the polynomials is a field. For non-field polynomials, one has to replace the modulo operation by the pseudo-modulo operation, which results in the exponential growth of coefficients in the gcd algorithm. To counter this problem, one may divide the intermediate polynomials by their contents in every iteration of the gcd algorithm. This is precisely the way how currently resultants and gcds are computed in Isabelle.

Computing contents in every iteration is a costly operation, and therefore Brown and Traub have developed the subresultant PRS (polynomial remainder sequence) algorithm [1, 2]. It avoids intermediate content computation and at the same time keeps the coefficients small, i.e., the coefficients grow at most polynomially.

The soundness of the subresultant PRS gcd algorithm is in principle similar to the Euclidean algorithm, i.e., the intermediate polynomials that are computed in both algorithms differ only by a constant factor. The major problem is to prove that all the performed divisions are indeed exact divisions. To this end, we formalize the fundamental theorem of Brown and Traub as well as the resulting algorithms by following the original (condensed) proofs. This is in contrast to a similar Coq formalization by Mahboubi [4], which follows another proof based on polynomial determinants.

As a consequence of the new algorithms, we significantly increased the speed of the algebraic number implementation [5] which heavily relies upon the computation of resultants of bivariate polynomials.

2 Resultants

This theory defines the Sylvester matrix and the resultant and contains basic facts about these notions. After the connection between resultants and subresultants has been established, we then use properties of subresultants to transfer them to resultants. Remark: these properties have previously been proven separately for both resultants and subresultants; and this is the reason for splitting the theory of resultants in two parts, namely "Resultant-Prelim" and "Resultant" which is located in the Algebraic-Number AFP-entry.

6 Polynomial coefficients with integer index

We provide a function to access the coefficients of a polynomial via an integer index. Then index-shifting becomes more convenient, e.g., compare in the lemmas for accessing the coeffiencent of a product with a monomial there is no special case for integer coefficients, whereas for natural number coefficients there is a case-distinction.

7 Subresultants and the subresultant PRS

This theory contains most of the soundness proofs of the subresultant PRS algorithm, where we closely follow the papers of Brown [1] and Brown and Traub [2]. This is in contrast to a similar Coq formalization of Mahboubi [4] which is based on polynomial determinants.

Whereas the current file only contains an algorithm to compute the resultant of two polynomials efficiently, there is another theory "Subresultant-Gcd" which also contains the algorithm to compute the GCD of two polynomials via the subresultant algorithm. In both algorithms we integrate Lazard's optimization in the dichotomous version, but not the second optmization described by Ducos [3].

7.3 Code Equations

In the following code-equations, we only compute the required values, e.g., h_k is not required if $n_k > 0$, we compute $(-1)^{\cdots} * \ldots$ via a case-analysis, and we perform special cases for $\delta_i = 1$, which is the most frequent case.

8 Computing the Gcd via the subresultant PRS

This theory now formalizes how the subresultant PRS can be used to calculate the gcd of two polynomials. Moreover, it proves the connection between resultants and gcd, namely that the resultant is 0 iff the degree of the gcd is non-zero.

theory *Subresultant-Gcd*

Note that we did not activate *gcd* = *gcd-impl-Lazard* as code-equation, since according to our experiments, the subresultant-gcd algorithm is not always more efficient than the currently active equation. In particular, on *int poly gcd-impl-Lazard* performs worse, but on multi-variate polynomials, e.g., *int poly poly poly*, *gcd-impl-Lazard* is preferable.

end
